

## ON A TAYLOR REMAINDER

LARS-ERIK PERSSON AND HUMBERTO RAFEIRO

ABSTRACT. In this note we derive a new Taylor remainder, which extends the well known Lagrange remainder as well as the obscure Gonçalves remainder.

### 1. INTRODUCTION

The Taylor formula is one of the most well-known results in analysis. The Lagrange, Cauchy and Peano remainders are well-known but there are other less known Taylor remainders e.g. Schlömilch, Bourget, Blumenthal and Gonçalves among others, see [2] for a detailed review and historical remarks on these remainders.

### 2. NEW TAYLOR REMAINDER

Since our main result depends crucially on the Cauchy generalized mean value theorem, we give its exact formulation taken from [3, Theorem 5.9]:

CAUCHY GENERALIZED MEAN VALUE THEOREM: *If  $f$  and  $g$  are continuous real functions on  $[a, b]$  which are differentiable in  $(a, b)$ , then there is a point  $x \in (a, b)$  at which*

$$[f(b) - f(a)]g'(x) = [g(b) - g(a)]f'(x).$$

Note that differentiability is not required at the end points. Moreover, if  $g'(\tau) \neq 0$  for all  $\tau \in (a, b)$  then we have the equality

$$(1) \quad \frac{f(b) - f(a)}{g(b) - g(a)} = \frac{f'(x)}{g'(x)}.$$

We highlight the fact that  $g'(\xi)$  can be zero in  $\xi = a$  or  $\xi = b$ , since the conditions in the Cauchy generalized mean value theorem only require that  $g'(\xi) \neq 0$  in  $(a, b)$ . For a recent work on mean value theorem we refer the reader to [1].

The following observation will be useful. Let  $\varphi$  be continuous in  $[a, b]$  and differentiable in  $(a, b)$  such that  $\varphi(x) \neq 0$  for all  $x \in (a, b)$ . If  $\varphi'(\xi)R(\xi)$  has a primitive  $\psi(\xi)$ , then by the Cauchy generalized mean value theorem we get

$$(2) \quad \frac{\psi(b) - \psi(a)}{\varphi(b) - \varphi(a)} = \frac{\psi'(\xi)}{\varphi'(\xi)} = R(\xi),$$

where  $\xi$  lies between  $b$  and  $a$ .

Our main results reads:

**Theorem 1.** *Let  $f^{(j)}$  and  $\varphi^{(j)}$  be real-valued continuous functions in  $[\alpha, \beta]$  and differentiable in  $(\alpha, \beta)$  for  $j = 0, \dots, n-1$ . Then, for  $a \in [\alpha, \beta]$  and all  $x \in [\alpha, \beta] \setminus \{a\}$  and  $\varphi = \varphi(x)$  such that  $\varphi^{(s)}(\xi) \neq 0$  for all  $\xi$  lying between  $a$  and  $x$  and for  $s = 1, \dots, n$  we have*

$$(3) \quad f(x) = f(a) + f'(a)(x-a) + \dots + \frac{f^{(n)}(a)}{n!}(x-a)^n + r_n(x; a),$$

with

$$(4) \quad r_n(x; a) = \left( \varphi(x) - \sum_{k=0}^{n-1} \frac{(x-a)^k}{k!} \varphi^{(k)}(a) \right) \left( \frac{f^{(n)}(\xi) - f^{(n)}(a)}{\varphi^{(n)}(\xi)} \right),$$

where  $x \neq a$  and  $\xi$  lies between  $a$  and  $x$ .

*Proof.* Let  $x > a$  and define  $R(x)$  as

$$(5) \quad f^{(n)}(x) - f^{(n)}(a) = \varphi^{(n)}(x)R(x).$$

Applying (2) to (5) we obtain

$$(6) \quad f^{(n-1)}(x) - f^{(n-1)}(a) - (x-a)f^{(n)}(a) = [\varphi^{(n-1)}(x) - \varphi^{(n-1)}(a)](R \circ \vartheta_1)(x),$$

where  $\vartheta_1(x) = a + \theta_1(x)(x-a)$  and  $\theta_1(x) \in (0, 1)$ . Applying again (2) to (6) we obtain

$$\begin{aligned} f^{(n-2)}(x) - f^{(n-2)}(a) - (x-a)f^{(n-1)}(a) - \frac{(x-a)^2}{2}f^{(n)}(a) \\ = [\varphi^{(n-2)}(x) - \varphi^{(n-2)}(a) - (x-a)\varphi^{(n-1)}(a)](R \circ \vartheta_1 \circ \vartheta_2)(x) \end{aligned}$$

where  $\vartheta_2(x) = a + \theta_2(x)(x-a)$  and  $\theta_2(x) \in (0, 1)$ .

Now iterating the previous reasoning we finally obtain

$$f(x) = f(a) + (x-a)f'(a) + \dots + \frac{(x-a)^n f^{(n)}(a)}{n!} + \left[ \varphi(x) - \sum_{k=0}^{n-1} \frac{(x-a)^k}{k!} \varphi^{(k)}(a) \right] (R \circ \vartheta_1 \circ \dots \circ \vartheta_n)(x)$$

from which we get the desired result since  $R(x) = \frac{f^{(n)}(x) - f^{(n)}(a)}{\varphi^{(n)}(x)}$ . The case of  $x < a$  is similar.  $\square$

*Remark 1.* Taking  $\varphi(\kappa) = (\kappa - a)^{n+1}$  we obtain the Gonçalves remainder (see [2] for an historical account on this remainder)

$$(7) \quad r_n(x; a) = \frac{(x-a)^{n+1}}{(n+1)!} \left( \frac{f^{(n)}(\xi) - f^{(n)}(a)}{\xi - a} \right),$$

and if  $f$  has  $n+1$  derivatives it follows from (7) and the Lagrange mean value theorem the well-known Lagrange remainder.

Since in the  $n$ th remainder (4) we only ask for the existence of the derivative of  $f$  up to order  $n$  instead of up to order  $n+1$  as in the case of Lagrange, Cauchy, Schlömilch, etc., the remainder (4) gives a theoretical improvement. Let us give an example.

*Example 1.* Taking  $f(x) = \frac{1}{2}x^2 \operatorname{sign}(x)$  and remembering that  $f'(x) = |x|$ , we now calculate the Taylor formula with two different remainders.

For  $x < 0$  and  $a = 1$ , we have the Taylor formula with Lagrange remainder of  $f$  given by

$$f(x) = \frac{1}{2} + (x-1)|\xi|, \quad \xi \in (x, 1),$$

whereas taking the Taylor formula with Gonçalves remainder (7) we obtain

$$f(x) = \frac{1}{2} + (x-1) + \frac{(x-1)^2}{2} \left( \frac{|\xi| - 1}{\xi - 1} \right), \quad \xi \in (x, 1).$$

### 3. ACKNOWLEDGEMENTS

H.R. thanks *Luleå University of Technology* for financial support for research visit in January-February of 2016. The authors thank the anonymous referee for pointing us the reference [1].
