# Cyclic Compositions of a Positive Integer with Parts Avoiding an Arithmetic Sequence 

Petros Hadjicostas<br>School of Mathematics and Statistics<br>Victoria University of Wellington Wellington 6140<br>New Zealand<br>peterhadji1@gmail.com

#### Abstract

A linear composition of a positive integer $n$ is a finite sequence of positive integers (called parts) whose sum equals $n$. A cyclic composition of $n$ is an equivalent class of all linear compositions of $n$ that can be obtained from each other by a cyclic shift. In this paper, we enumerate the cyclic compositions of $n$ that avoid an increasing arithmetic sequence of positive integers. In the case where all multiples of a positive integer $r$ are avoided, we show that the number of cyclic compositions of $n$ with this property equals to or is one less than the number of cyclic zero-one sequences of length $n$ that do not contain $r$ consecutive ones. In addition, we show that this number is related to the $r$-step Lucas numbers.

## 1 Introduction

Beck and Robbins [4] use generating functions to give an alternative proof of a result by Robbins [21, 22] regarding the number of $r$-regular (linear) compositions of a positive integer $n$. By a (linear) composition of a positive integer $n$ of length $k$ we mean a $k$-tuple $\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\right) \in \mathbb{Z}_{>0}^{k}$ such that

$$
\begin{equation*}
n=\lambda_{1}+\lambda_{2}+\cdots+\lambda_{k} \tag{1}
\end{equation*}
$$

Here the numbers $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}$ are called the parts of the composition. By an $r$-regular (linear) composition of $n$ with length $k$ we mean a composition $\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\right)$ of $n$ such that
none of its parts are positive multiples of $r$. A result that appears in Beck and Robbins [4] and Robbins [21, 22], and which is stated as Theorem 5 in this paper, gives linear recursive formulas for the number of $r$-regular linear compositions of $n$.

In this paper, we state and prove a similar result for $r$-regular cyclic compositions (see Theorem 7). To achieve that, we first provide a formula for the number of cyclic compositions of a positive integer $n$ with length $k$ whose parts belong to a set $A \subseteq \mathbb{Z}_{>0}$. See formula (4) in Theorem 1. This formula is a generalization of formulas found by Sommerville [23] more than a century ago (see below).

Cyclic compositions of length $k$ of positive integer $n$ can be defined as equivalent classes on the set of all linear compositions of $n$ with length $k$ such that two compositions belong to the same class if and only if one can be obtained from the other by a cyclic shift. If $\left(\lambda_{1}, \ldots, \lambda_{k}\right)$ is a representative of an equivalent class, we denote the class by $\left[\left(\lambda_{1}, \ldots, \lambda_{k}\right)\right]_{R}$. For example, if $n=4$, then we have five equivalent classes (cyclic compositions):

$$
\begin{array}{cc}
\text { (i) }[(4)]_{R}, & \text { (ii) }[(1,3)]_{R}=[(3,1)]_{R}, \\
\text { (iii) }[(2,2)]_{R}, \\
\text { (iv) }[(1,1,2)]_{R}=[(2,1,1)]_{R}=[(1,2,1)]_{R}, & \text { (iv) }[(1,1,1,1)]_{R} .
\end{array}
$$

Given a set $A \subseteq \mathbb{Z}_{>0}$, we denote by $c_{A}^{L}(n ; k)$ and $c_{A}^{R}(n ; k)$ the number of linear and cyclic compositions, respectively, of length $k$ of positive integer $n$ with parts in $A$. We also let

$$
c_{A}^{L}(n)=\sum_{k=1}^{n} c_{A}^{L}(n ; k) \quad \text { and } \quad c_{A}^{R}(n)=\sum_{k=1}^{n} c_{A}^{R}(n ; k) .
$$

When $A=\mathbb{Z}_{>0}$, it was proven by MacMahon [16], and probably others before him, that (for $1 \leq k \leq n$ )

$$
\begin{equation*}
c_{\mathbb{Z}_{>0}}^{L}(n ; k)=\binom{n-1}{k-1} \quad \text { and } \quad c_{\mathbb{Z}}^{>0}(n)=2^{n-1} \tag{2}
\end{equation*}
$$

Similarly, it was proven by Sommerville [23] that, when $n$ is prime and $1 \leq k<n$,

$$
c_{\mathbb{Z}}^{R}(n ; k)=\frac{1}{n}\binom{n}{k} .
$$

When $n=2^{m}$ for some positive integer $m$ and $k$ is an odd positive integer less than $n$, he proved that

$$
c_{\mathbb{Z}}^{R}(n ; k)=\frac{1}{2^{m}}\binom{2^{m}}{k} .
$$

Sommerville's [23] results were generalized more than seven decades later by Razen et al. [20]; also see [2], [7, p. 48], [14], [24, pp. 70-71], and [25]. In these references, it is proven that (for $1 \leq k \leq n$ )

$$
\begin{equation*}
c_{\mathbb{Z}}^{R}(n ; k)=\frac{1}{n} \sum_{j \mid \operatorname{gcd}(n, k)} \phi(j)\binom{n / j}{k / j} \quad \text { and } \quad c_{\mathbb{Z}_{>0}}^{R}(n)=-1+\frac{1}{n} \sum_{j \mid n} \phi(j) 2^{\frac{n}{j}}, \tag{3}
\end{equation*}
$$

where $\phi(n)$ is Euler's totient function at $n$. (Here the summation ranges over all positive divisors $j$ of $\operatorname{gcd}(n, k)$ in the first sum and all positive divisors $j$ of $n$ is the second sum.) The numbers $\left(c_{\mathbb{Z}}^{R}(n): n \in \mathbb{Z}_{>0}\right)$ appear in A037306. We generalize equations (3) to the case when $A$ is any subset of $\mathbb{Z}_{>0}$; see equations (4) and (5) in this paper.

We also prove that the number of cyclic $r$-regular compositions of $n$ is closely related to the number of cyclic $0-1$ sequences of length $n$ that do not contain $r$ consecutive ones; see Theorem 7. A $0-1$ sequence of length $n$, say $\left(\delta_{1}, \ldots, \delta_{n}\right)$ with $\delta_{i} \in\{0,1\}$ for $i=1,2, \ldots, n$, gives rise to a cyclic sequence $\left[\left(\delta_{1}, \ldots, \delta_{n}\right)\right]_{R}$ in the same way cyclic compositions were defined above. For example, there are 4 cyclic $0-1$ sequences of length 3 :

$$
\begin{aligned}
& \text { (i) }[(0,0,0)]_{R}, \quad \text { (ii) }[(1,0,0)]_{R}=[(0,1,0)]_{R}=[(0,0,1)]_{R}, \\
& \text { (iii) }[(0,1,1)]_{R}=[(1,0,1)]_{R}=[(1,1,0)]_{R}, \quad \text { (iv) }[(1,1,1)]_{R} \text {. }
\end{aligned}
$$

The total number of $0-1$ cyclic sequences of length $n$ is $c_{\mathbb{Z}}^{R}(n)+1$. This was proven by MacMahon [15]. See also Bender [5] and Zhang and Hadjicostas [26].

If in a cyclic $0-1$ sequence $\left[\left(\delta_{1}, \ldots, \delta_{n}\right)\right]_{R}$ we identify 1 with a black bead and 0 with a white bead, then we get a (fixed) necklace with $n$ beads; e.g., see Graham et al. [9, Section 4.9]. In Knopfmacher and Robbins [14], a bijection is given between necklaces of $n$ beads with $k$ black and $n-k$ white beads, and cyclic compositions of $n$ with $k$ parts. This bijection, however, does not seem to help in establishing a connection between the number of cyclic $r$-regular compositions of $n$ with the number of $0-1$ cyclic sequences of length $n$ that do not contain $r$ consecutive ones, which is one the main topics of this paper. The bijection in Knopfmacher and Robbins [14] does, however, prove that the number of necklaces with $n$ beads of which $k$ are black and the rest white is given by the number $c_{\mathbb{Z}>0}^{R}(n ; k)$. In addition, it also establishes MacMahon's [15] result that the total number of necklaces with $n$ beads which are either black or white is $c_{\mathbb{Z}}^{R}(n)+1$ (where the extra 1 corresponds to the necklace consisting of $n$ white beads).

The organisation of the paper is as follows. In Section 2, we first provide a formula that connects $c_{A}^{R}(n ; k)$ to $c_{A}^{L}(n / s ; k / s)$, where $s$ ranges over the common divisors of $n$ and $k$. We also provide a formula that connects $c_{A}^{R}(n)$ to $c_{A}^{L}(n / s)$, where $s \mid n$, through a sequence of integers $\left(g_{A}(n): n \in \mathbb{Z}_{>0}\right)$, which is interesting on its own right. We provide a generating function and recursive formulas for this sequence of integers (see Lemma 2). Using these results, we provide a generating function for the numbers $c_{A}^{R}(n)$ (see Corollary 4), and we mention that this generating function is reminiscent of the theory in Flajolet and Soria [8]. For the case when $A$ is the set of positive integers that avoid all multiples of a fixed integer, we remind the reader of a theorem in Beck and Robbins [4] and Robbins [22] that provides recursive formulas for the numbers $c_{A}^{L}(n)$, and then (in Corollary 6) we proceed to state a similar theorem for the numbers $g_{A}(n)$. This result involves the generalized Lucas numbers. In Theorem 8, we correct a result that appeared in Beck and Robbins [4] for the case when $A$ avoids an increasing arithmetic sequence, and we state a similar result for the numbers $g_{A}(n)$ in Corollary 9.

The proofs of most results in Section 2 appear in Section 3 of the paper. Section 4 contains examples that illustrate the theory and results of this paper, while Section 5 contains some concluding remarks.

Note that some of the sequences in this paper maybe shifted versions of the corresponding cited sequences in OEIS [1]. Not all authors agree on what is the first term of each sequence.

## 2 The main results

The following theorem connects the numbers of linear and cyclic compositions of $n$ with parts in $A$, and it allows us to prove our claims in this paper. This result is important because the theory of enumeration of all linear compositions with parts in $A$ is more wellestablished $[11,12]$ than the corresponding theory for the enumeration of cyclic compositions with parts in $A$. (Proofs of the results in this section, which have not been proven elsewhere, appear in the next section of the paper.)
Theorem 1. The number of cyclic compositions of $n$ of length $k$ with parts in $A$ is given by

$$
\begin{equation*}
c_{A}^{R}(n ; k)=\frac{1}{k} \sum_{s \mid \operatorname{gcd}(n, k)} \phi(s) c_{A}^{L}\left(\frac{n}{s} ; \frac{k}{s}\right) . \tag{4}
\end{equation*}
$$

Also, the total number of cyclic compositions (of any length) of $n$ with parts in $A$ is

$$
\begin{equation*}
c_{A}^{R}(n)=\frac{1}{n} \sum_{d \mid n} \phi(d) g_{A}\left(\frac{n}{d}\right), \tag{5}
\end{equation*}
$$

where

$$
\begin{equation*}
g_{A}(s)=s \sum_{k=1}^{s} \frac{c_{A}^{L}(s ; k)}{k} \quad \text { for } s \in \mathbb{Z}_{>0} \tag{6}
\end{equation*}
$$

The numbers $\left(g_{A}(n): n \in \mathbb{Z}_{>0}\right)$ are used throughout this paper, and they satisfy some useful recurrences; see equations (8) and (9) in the lemma below.
Lemma 2. The generating function of the numbers $g_{A}(n)$ is given by

$$
\begin{equation*}
\sum_{n \geq 1} g_{A}(n) x^{n}=\frac{\sum_{s \in A} s x^{s}}{1-\sum_{s \in A} x^{s}} \tag{7}
\end{equation*}
$$

For each positive integer n,

$$
\begin{equation*}
g_{A}(n)=\sum_{s=1}^{n-1} g_{A}(s) I(n-s \in A)+n I(n \in A) \tag{8}
\end{equation*}
$$

and

$$
\begin{equation*}
g_{A}(n)=\sum_{s=1}^{n-1} s I(s \in A) c_{A}^{L}(n-s)+n I(n \in A) \tag{9}
\end{equation*}
$$

where $I(x \in A)=1$ if $x \in A$, and zero otherwise.

Since an empty sum is by definition zero, equations (8) and (9) in Lemma 2 give $g_{A}(1)=$ $I(1 \in A)$. This of course agrees with the equation $g_{A}(1)=c_{A}^{L}(1 ; 1)=I(1 \in A)$.
Remark 3. Using the generating function of the numbers $c_{A}^{L}(n)$ (see Beck and Robbins [4] and Moser and Whitney [18], or see equation (22) in this paper), one can easily show that, for $n \in \mathbb{Z}_{>0}$,

$$
\begin{equation*}
c_{A}^{L}(n)=\sum_{s=1}^{n-1} c_{A}^{L}(s) I(n-s \in A)+I(n \in A) \tag{10}
\end{equation*}
$$

The following result is reminiscent of the theory in Flajolet and Sedgewick [7, pp. 27 and 729-730] and Flajolet and Soria [8] about the generating function of cycles of unlabelled combinatorial structures, but we derive it independently using Theorem 1 and Lemma 2 above.

Corollary 4. The generating function of the total number of cyclic compositions (of any length) of $n$ with parts in $A$, i.e., $c_{A}^{R}(n)$, is

$$
\sum_{n \geq 1} c_{A}^{R}(n) x^{n}=\sum_{n \geq 1} \frac{\phi(n)}{n} \log \frac{1}{1-\sum_{s \in A} x^{s n}}
$$

Robbins [22] and Beck and Robbins [4] have shown the following result for the special case when we count all $r$-regular linear compositions of $n$.

Theorem 5. If $r$ is a fixed positive integer and $A$ is the set all of positive integers that are not multiples of $r$, then the number of linear compositions of $n$ with parts in $A$, i.e., $c_{A}^{L}(n)$, is given by the sequence $\left(f_{n}: n \in \mathbb{Z}_{>0}\right)$ defined recursively through

$$
\begin{aligned}
& f_{j}=2^{j-1} \quad \text { for } 1 \leq j \leq r-1 \\
& f_{r}=2^{r-1}-1 \\
& f_{j}=f_{j-1}+f_{j-2}+\cdots+f_{j-r} \quad \text { for } j>r
\end{aligned}
$$

Clearly, for $r=1$ the sequence ( $f_{n}: n \in \mathbb{Z}_{>0}$ ) is a sequence of 0 's. As noted in Beck and Robbins [4], the case $r=2$ gives rise to the Fibonacci numbers, while the cases $r=3$ and $r=4$ give rise to one version of Tribonacci and Tetranacci numbers, that is, A001590 and A001631, respectively. These sequences should not be confused, however, with the Tribonacci and Tetranacci sequences $\underline{A 000073}$ and $\underline{A 000078}$, respectively, which are special cases of the $r$-step (or $r$-generalized) Fibonacci sequences, which are mentioned, for example, in Miles [17] and Zhang and Hadjicostas [26]. These $r$-step Fibonacci sequences are first cousins of the $r$-step Lucas numbers defined below, which are needed in this paper.

For positive integer $r$, following Noe and Vos Post [19] and Zhang and Hadjicostas [26], we may define the $r$-generalized Lucas numbers $\left(L_{n}^{(r)}: n \in \mathbb{Z}\right)$ by

$$
\begin{equation*}
L_{n}^{(r)}=-1 \quad \text { for } n<0, \quad L_{0}^{(r)}=r \tag{11}
\end{equation*}
$$

and by the recursion

$$
\begin{equation*}
L_{n}^{(r)}=\sum_{i=1}^{r} L_{n-i}^{(r)} \quad \text { for all } n \geq 1 \tag{12}
\end{equation*}
$$

For $r=1$, starting from $n=0$, we get a sequence of 1 's, while the case $r=2$ corresponds to A000032, and it is the usual Lucas sequence. Starting at $n=0$, the cases $r=3$ and $r=4$ correspond to $\underline{\text { A001644 }}$ and A073817, respectively.

Corollary 6. Let $r$ be a fixed positive integer and $A$ be the set all of positive integers that are not multiples of $r$. Then the sequence

$$
\left(g_{A}(n)+r I(r \mid n): n \in \mathbb{Z}_{>0}\right)
$$

satisfies the same $r$-order recurrence that the sequence $\left(c_{A}^{L}(n): n \in \mathbb{Z}_{>0}\right)$ satisfies in Theorem 5, but (in general) with different initial conditions. More specifically,

$$
g_{A}(n)=L_{n}^{(r)}-r I(r \mid n) \quad \text { for all } n \in \mathbb{Z}_{>0}
$$

Let $\rho_{n}^{(r)}$ be the number of cyclic sequences of length $n$ consisting of 0 's and 1 's that do not contain $r$ consecutive 1's. For example, $\rho_{4}^{(3)}=4$ because we have the following cyclic sequences of length $n=4$ that avoid $r=3$ consecutive 1 's:
(i) $[(0,0,0,0)]_{R}$,
(ii) $[(0,0,0,1)]_{R}$,
(iii) $[(0,0,1,1)]_{R}$,
(iv) $[(0,1,0,1)]_{R}$.
(To be able to define $\rho_{n}^{(r)}$ for any $n, r \in \mathbb{Z}_{>0}$, we make the convention that a sequence of length $n$ with all 1's contains $r$ consecutive 1's even if $n<r$.) For $r=2$ and $r=3$ the sequences of numbers $\rho_{n}^{(r)}$ appear in A000358 and A093305, respectively.

Using Theorem 1, Corollary 6, and a result from Zhang and Hadjicostas [26], we prove in the next section the following theorem.

Theorem 7. If $r$ is a fixed positive integer and $A$ is the set all of positive integers that are not multiples of $r$, then the number of cyclic compositions of $n$ with parts in $A$, i.e., $c_{A}^{R}(n)$, is given by

$$
\begin{equation*}
c_{A}^{R}(n)=-I(r \mid n)+\frac{1}{n} \sum_{d \mid n} \phi\left(\frac{n}{d}\right) L_{d}^{(r)}=-I(r \mid n)+\rho_{n}^{(r)} \tag{13}
\end{equation*}
$$

where $I(r \mid n)=1$ if $r \mid n$, and zero otherwise.
In other words, the previous theorem says that when $r$ does not divide $n$, the number of $r$-regular cyclic compositions of $n$ equals the number of cyclic sequences of length $n$ consisting of 0's and 1's that not contain $r$ consecutive 1's. Otherwise, if $r$ divides $n$, then $c_{A}^{(R)}(n)=\rho_{n}^{(r)}-1$.

When $A$ is the set of all positive integers that do not include any member of an increasing arithmetic sequence, say of the form $m+j r$ for $j \in \mathbb{Z}_{\geq 0}$, where $r$ and $m$ are positive integers
with $m<r$, we may derive a result like Corollary 6 above, but not as elegant. This is done in Corollary 9 below.

Before we do that, we remind the reader of a result in Beck and Robbins [4] about the number of linear compositions of $n$ with parts that are not members of an increasing arithmetic sequence of positive integers. Unfortunately, some of the initial conditions in the recurrence in Theorem 4 in Beck and Robbins [4] are not correct, so we correct them here. The proof of the corrected Theorem 4, stated as Theorem 8 below, is similar to the proofs in Beck and Robbins [4], and hence it is omitted; one can also prove it using equation (10) in this paper. (The notation $B-C$ denotes set difference between the sets $B$ and $C$.)

Theorem 8. Let $r$ and $m$ be fixed integers with $1 \leq m<r$, and let

$$
\begin{equation*}
A=\mathbb{Z}_{>0}-\left\{m+j r: j \in \mathbb{Z}_{\geq 0}\right\} \tag{14}
\end{equation*}
$$

Then the number of linear compositions of $n$ with parts in $A$, i.e., $c_{A}^{L}(n)$, is given by the sequence $\left(f_{n}: n \in \mathbb{Z}_{>0}\right)$ defined recursively through

$$
\begin{aligned}
f_{n} & =2^{n-1} \quad \text { for } 1 \leq n \leq m-1 \\
f_{m} & =2^{m-1}-1 \\
f_{n} & =\sum_{\substack{i=1 \\
i \neq m}}^{n-1} f_{n-i}+1 \quad \text { for } m+1 \leq n \leq r, \\
f_{n} & =\sum_{\substack{i=1 \\
i \neq m}}^{r-1} f_{n-i}+2 f_{n-r} \quad \text { for } n>r .
\end{aligned}
$$

Using Lemma 2, we can prove the result below. Here, $I[n \not \equiv m(\bmod r)]=1$ when $r$ does not divide $n-m$, and zero otherwise.

Corollary 9. Let $r$ and $m$ be fixed integers with $1 \leq m<r$, and assume $A$ is given by equation (14). Then the sequence $\left(g_{A}(n): n \in \mathbb{Z}_{>0}\right)$ satisfies

$$
\begin{aligned}
g_{A}(n) & =2^{n}-1 \quad \text { for } 1 \leq n \leq m-1, \\
g_{A}(m) & =2^{m}-m-1, \\
g_{A}(n) & =\sum_{\substack{i=1 \\
i \neq m}}^{n-1} g_{A}(n-i)+n \quad \text { for } m+1 \leq n \leq r, \\
g_{A}(n) & =\sum_{\substack{i=1 \\
i \neq m}}^{r-1} g_{A}(n-i)+2 g_{A}(n-r)+r I[n \not \equiv m(\bmod r)] \quad \text { for } n>r .
\end{aligned}
$$

There is some similarity between the four equalities in Theorem 8 and those in Corollary 9, but the two results yield different sequences (for fixed values of $m$ and $r$ ). For example, when
$m=1<r$, the sequence $\left(f_{n}: n \in \mathbb{Z}_{>0}\right)$ in Theorem 8 is defined through

$$
f_{1}=0, \quad f_{n}=\sum_{i=2}^{n-1} f_{n-i}+1 \quad \text { for } 2 \leq n \leq r
$$

and

$$
f_{n}=\sum_{i=2}^{r-1} f_{n-i}+2 f_{n-r} \quad \text { for } n \geq r+1
$$

On the other hand, the sequence $\left(g_{A}(n): n \in \mathbb{Z}_{>0}\right)$ in Corollary 9 is defined through

$$
g_{A}(1)=0, \quad g_{A}(n)=\sum_{i=2}^{n-1} g_{A}(n-i)+n \quad \text { for } 2 \leq n \leq r
$$

and

$$
g_{A}(n)=\sum_{i=2}^{r-1} g_{A}(n-i)+2 g_{A}(n-r)+r I(r \nmid n-1) \quad \text { for } n>r .
$$

## 3 Proofs

In this section we prove Theorems 1 and 7, Corollaries 4, 6 and 9, and Lemma 2 from the previous section. Before we do that, we illustrate that Theorem 1 works even when $A=\mathbb{Z}_{>0}$. Equation (4) in Theorem 1 becomes

$$
\begin{gathered}
c_{A}^{R}(n, k)=\frac{1}{k} \sum_{s \mid \operatorname{gcd}(n, k)} \phi(s)\binom{(n / s)-1}{(k / s)-1} \\
=\frac{1}{n} \sum_{s \mid \operatorname{gcd}(n, k)} \phi(s) \frac{n / s}{k / s}\binom{(n / s)-1}{(k / s)-1}=\frac{1}{n} \sum_{s \mid \operatorname{gcd}(n, k)} \phi(s)\binom{n / s}{k / s},
\end{gathered}
$$

which is the first equation in (3). Also, when $A=\mathbb{Z}_{>0}$, we can use the first equation in (2) and equation (6) to obtain

$$
\begin{equation*}
g_{A}(n)=n \sum_{k=1}^{n} \frac{\binom{n-1}{k-1}}{k}=2^{n}-1 . \tag{15}
\end{equation*}
$$

We leave it to the reader to prove the second equation in (15); e.g. use the binomial theorem and integration. It follows from Theorem 1 that

$$
c_{A}^{R}(n)=\frac{1}{n} \sum_{d \mid n} \phi(d)\left(2^{n / d}-1\right)=\frac{1}{n} \sum_{d \mid n} \phi(d) 2^{n / d}-\frac{1}{n} \sum_{d \mid n} \phi(d),
$$

which gives the second equation in (3) because $\sum_{d \mid n} \phi(d)=n$; see Apostol [3, Section 2.3].

Proof of Theorem 1. Consider an arbitrary circular composition $\left[\left(\lambda_{1}, \ldots, \lambda_{k}\right)\right]_{R}$ of $n$ with length $k$ and with parts in $A$. Place the $\lambda_{i}$ 's of this composition on a circle (i.e., $\lambda_{1}$ follows $\left.\lambda_{n}\right)$. We define the period $h$ of this circular composition to be the length of the shortest subsequence of $\lambda_{i}$ 's with consecutive indices that is able to re-produce $\left[\left(\lambda_{1}, \ldots, \lambda_{k}\right)\right]_{R}$ by repeating itself $k / h$ times. Because of equation (1), we must have that the positive integer $k / h$ divides $n$.

The set of all linear compositions of $n$ with length $k$ and parts in $A$ can be partitioned into equivalent classes representing all circular compositions of $n$ with length $k$ and parts in $A$. These equivalent classes can be classified according to their period $h$, and each equivalent class with period $h$ produces exactly $h$ linear compositions of $n$ with length $k$ and with parts in $A$. If we denote by $c_{A}^{R}(n ; k ; h)$ the number of all circular compositions of $n$ with length $k$, period $h$, and parts in $A$, then

$$
c_{A}^{L}(n ; k)=\sum_{h\left|k \& \frac{k}{h}\right| n} h c_{A}^{R}(n ; k ; h) .
$$

Let $s=\frac{k}{h}$, in which case

$$
\begin{equation*}
c_{A}^{L}(n ; k)=\sum_{s \mid \operatorname{gcd}(n, k)} \frac{k}{s} c_{A}^{R}\left(n ; k ; \frac{k}{s}\right)=\sum_{s \mid \operatorname{gcd}(n, k)} \frac{k}{s} c_{A}^{R}\left(\frac{n}{s} ; \frac{k}{s} ; \frac{k}{s}\right) . \tag{16}
\end{equation*}
$$

The last step follows from the fact that a circular composition of $n$ with length $k$ and period $k / s$ can be partitioned into $s$ identical circular compositions of $n / s$ with length $k / s$ and period $k / s$. Similarly,

$$
\begin{aligned}
c_{A}^{R}(n ; k) & =\sum_{h \left\lvert\, k \& \frac{k}{h \mid n}\right.} c_{A}^{R}(n ; k ; h) \\
& =\sum_{s \mid \operatorname{gcd}(n, k)} c_{A}^{R}\left(n ; k ; \frac{k}{s}\right)=\sum_{s \mid \operatorname{gcd}(n, k)} c_{A}^{R}\left(\frac{n}{s} ; \frac{k}{s} ; \frac{k}{s}\right) .
\end{aligned}
$$

Letting $a=\operatorname{gcd}(n, k), n^{*}=n / a, k^{*}=k / a$, and $v=a / s$, we get

$$
\begin{equation*}
c_{A}^{R}\left(n^{*} a, k^{*} a\right)=\sum_{s \mid a} c_{A}^{R}\left(\frac{n^{*} a}{s} ; \frac{k^{*} a}{s} ; \frac{k^{*} a}{s}\right)=\sum_{v \mid a} c_{A}^{R}\left(n^{*} v ; k^{*} v ; k^{*} v\right) \tag{17}
\end{equation*}
$$

and

$$
\begin{equation*}
c_{A}^{L}\left(n^{*} a ; k^{*} a\right)=\sum_{v \mid a} k^{*} v c_{A}^{R}\left(n^{*} v ; k^{*} v ; k^{*} v\right) . \tag{18}
\end{equation*}
$$

Fixing $n^{*}$ and $k^{*}$ while varying $a$ (and this can be done because $n$ and $k$ are arbitrary positive integers with $1 \leq k \leq n$ ), we apply the Möbius 'inversion principle' on equation (18); see Graham et al. [9, Section 4.9]. We then get, for $v \in \mathbb{Z}_{>0}$,

$$
\begin{equation*}
k^{*} v c_{A}^{R}\left(n^{*} v ; k^{*} v ; k^{*} v\right)=\sum_{w \mid v} \mu(w) c_{A}^{L}\left(\frac{n^{*} v}{w} ; \frac{k^{*} v}{w}\right) . \tag{19}
\end{equation*}
$$

Here $\mu(d)$ is the Möbius function at integer $d$, which equals 1 if $d$ is square-free with an even number of prime factors, -1 if $d$ is square-free with an odd number of prime factors, and 0 otherwise; e.g., see Apostol [3, Chapter 2].

It follows from equations (17) and (19) that

$$
\begin{aligned}
c_{A}^{R}\left(n^{*} a, k^{*} a\right) & =\sum_{v \mid a} \frac{1}{k^{*} v} \sum_{w \mid v} \mu(w) c_{A}^{L}\left(\frac{n^{*} v}{w} ; \frac{k^{*} v}{w}\right) \\
& =\frac{1}{k^{*} a} \sum_{v \mid a} \frac{a}{v}\left(\sum_{w \mid v} \mu(w) c_{A}^{L}\left(\frac{n^{*} v}{w} ; \frac{k^{*} v}{w}\right)\right) \\
& =\frac{1}{k^{*} a} \sum_{v \mid a}\left(\sum_{w \mid v} \frac{v}{w} \mu(w)\right) c_{A}^{L}\left(\frac{n^{*} a}{v} ; \frac{k^{*} a}{v}\right) .
\end{aligned}
$$

The last step follows from the associativity of Dirichlet convolutions; see again Apostol [3, Chapter 2]. Using the formula

$$
v \sum_{w \mid v} \frac{\mu(w)}{w}=\phi(v)
$$

which is a standard result from Number Theory (e.g. see Apostol [3, Theorem 2.3]), we get

$$
c_{A}^{R}\left(n^{*} a, k^{*} a\right)=\frac{1}{k^{*} a} \sum_{v \mid a} \phi(v) c_{A}^{L}\left(\frac{n^{*} a}{v} ; \frac{k^{*} a}{v}\right) .
$$

Using the equalities $n=n^{*} a, k=k^{*} a$, and $a=\operatorname{gcd}(n, k)$ in the above equation, we obtain equation (4). The methodology we used above is due to Bender [5].

To prove equation (5) we sum both sides of (4) from $k=1$ to $k=n$ :

$$
c_{A}^{R}(n)=\sum_{k=1}^{n} c_{A}^{R}(n ; k)=\sum_{k=1}^{n} \sum_{d \mid \operatorname{gcd}(n, k)} \frac{1}{k} \phi(d) c_{A}^{L}\left(\frac{n}{d} ; \frac{k}{d}\right) .
$$

Letting $t=n / d$ and $\ell=k / d$, and switching the order of summation in the last double sum above, we get

$$
c_{A}^{R}(n)=\sum_{t \mid n} \sum_{\ell=1}^{t} \frac{\phi(n / t)}{\ell n / t} c_{A}^{L}(t ; \ell)=\frac{1}{n} \sum_{t \mid n} \phi\left(\frac{n}{t}\right) t \sum_{\ell=1}^{t} \frac{c_{A}^{L}(t ; \ell)}{\ell}
$$

Using equation (6), we can easily get equation (5).
Proof of Lemma 2. According to Beck and Robbins [4] and Hoggatt and Lind [13], the bivariate generating function of the numbers $c_{A}^{L}(n ; k)$ is given by

$$
\begin{equation*}
C_{A}^{L}(x, y)=1+\sum_{n, k \geq 1} c_{A}^{L}(n ; k) x^{n} y^{k}=\frac{1}{1-y \sum_{s \in A} x^{s}} \tag{20}
\end{equation*}
$$

which implies

$$
\sum_{n, k \geq 1} c_{A}^{L}(n ; k) x^{n} y^{k-1}=\frac{\sum_{s \in A} x^{s}}{1-y \sum_{s \in A} x^{s}}
$$

Integrating both sides of the above equation with respect to $y$, from 0 to $z$, we obtain

$$
\sum_{n \geq 1}\left(\sum_{k \geq 1} \frac{c_{A}^{L}(n ; k)}{k} z^{k}\right) x^{n}=\int_{0}^{z} \frac{\sum_{s \in A} x^{s}}{1-y \sum_{s \in A} x^{s}} d y=-\log \left(1-z \sum_{s \in A} x^{s}\right) .
$$

Setting $z=1$ in the above equations and differentiating with respect to $x$, we get

$$
\begin{equation*}
\sum_{n \geq 1} g_{A}(n) x^{n-1}=\frac{d}{d x}\left[-\log \left(1-\sum_{s \in A} x^{s}\right)\right]=\frac{\sum_{s \in A} s x^{s-1}}{1-\sum_{s \in A} x^{s}} . \tag{21}
\end{equation*}
$$

(Note that we have used the fact that $c_{A}^{L}(n ; k)=0$ for $k>n$.) This proves equation (7). Also,

$$
\left(\sum_{n \geq 1} g_{A}(n) x^{n}\right)\left(1-\sum_{s \geq 1} I(s \in A) x^{s}\right)=\sum_{s \geq 1} s I(s \in A) x^{s}
$$

Multiplying the two power series on the left-hand side of the above equation, and equating coefficients of $x^{s}$ from the resulting equality, we get

$$
g_{A}(s)-\sum_{t=1}^{s-1} g_{A}(t) I(s-t \in A)=s I(s \in A)
$$

and this proves equation (8).
Finally, we know from Beck and Robbins [4] and Moser and Whitney [18] that the generating function of the numbers $c_{A}^{L}(n)$ is

$$
\begin{equation*}
C_{A}^{L}(x)=1+\sum_{n \geq 1} c_{A}^{L}(n) x^{n}=\frac{1}{1-\sum_{s \in A} x^{m}} \tag{22}
\end{equation*}
$$

This of course follows from equation (20) by setting $y=1$, i.e.,

$$
C_{A}^{L}(x)=C_{A}^{L}(x, y=1)
$$

Using then equation (7), we obtain

$$
\left(\sum_{s \geq 1} s I(s \in A) x^{s}\right)\left(1+\sum_{n \geq 1} c_{A}^{L}(n) x^{n}\right)=\sum_{n \geq 1} g_{A}(n) x^{n}
$$

from which we can easily prove equation (9).

Proof of Corollary 4. Using Theorem 1, we have

$$
\sum_{n \geq 1} c_{A}^{R}(n) x^{n}=\sum_{n \geq 1} \frac{1}{n} \sum_{d \mid n} \phi(d) g_{A}\left(\frac{n}{d}\right) x^{n}
$$

We want to change the order of summation in the right-hand side of the above equation. We let $n=t d$, and then we have

$$
\begin{equation*}
\sum_{n \geq 1} c_{A}^{R}(n) x^{n}=\sum_{d \geq 1} \sum_{t \geq 1} \frac{\phi(d)}{t d} g_{A}(t) x^{t d}=\sum_{d \geq 1} \frac{\phi(d)}{d} \sum_{t \geq 1} \frac{g_{A}(t)}{t}\left(x^{d}\right)^{t} \tag{23}
\end{equation*}
$$

Integrating both sides of the first equation in (21) from $x=0$ to $x=z$, we obtain

$$
\begin{equation*}
\sum_{n \geq 1} \frac{g_{A}(n)}{n} z^{n}=-\log \left(1-\sum_{s \in A} z^{s}\right)=\log \frac{1}{1-\sum_{s \in A} z^{s}} \tag{24}
\end{equation*}
$$

Letting $z=x^{d}$, it then follows from equations (23) and (24) that

$$
\sum_{n \geq 1} c_{A}^{R}(n) x^{n}=\sum_{d \geq 1} \frac{\phi(d)}{d} \log \frac{1}{1-\sum_{s \in A} x^{s d}}
$$

and this completes the proof of the corollary.
Proof of Corollary 6. We note that equation (8) in Lemma 2 implies

$$
g_{A}(n)=\sum_{s=1}^{n-1} g_{A}(s) I(r \nmid n-s)+n I(r \nmid n) .
$$

Note that $r \nmid n-s$ if and only if $r \nmid n-r-s$, and $r \nmid n$ if and only if $r \nmid n-r$. Thus, for $n>r$,

$$
\begin{aligned}
g_{A}(n)= & \sum_{s=n-r+1}^{n-1} g_{A}(s)+\sum_{s=1}^{n-r-1} g_{A}(s) I(r \nmid n-r-s) \\
& +(n-r) I(r \nmid n-r)+r I(r \nmid n) \\
= & \sum_{s=n-r+1}^{n-1} g_{A}(s)+g_{A}(n-r)+r I(r \nmid n) \\
= & \sum_{s=n-r}^{n-1} g_{A}(s)+r I(r \nmid n) .
\end{aligned}
$$

It is then easy to prove that, for $n>r$,

$$
g_{A}(n)+r I(r \mid n)=\sum_{s=n-r}^{n-1}\left[g_{A}(s)+r I(r \mid s)\right]
$$

i.e., the sequence of numbers $\left(g_{A}(n)+r I(r \mid n): n \in \mathbb{Z}_{>0}\right)$ satisfies the same recurrence as the $r$-step Lucas numbers described by equations (11) and (12). In addition, if $1 \leq k \leq n \leq r$, then

$$
c_{A}^{L}(n ; k)=c_{\mathbb{Z}_{>0}}^{L}(n ; k)=\binom{n-1}{k-1}
$$

except when $n=r$ and $k=1$, in which case, $c_{A}^{L}(r ; 1)=0$. It follows from equation (15) that

$$
g_{A}(n)=2^{n}-1-r I(r \mid n)=L_{n}^{(r)}-r I(r \mid n) \quad \text { for } n=1,2, \ldots, r .
$$

Therefore, $g_{A}(n)=L_{n}^{(r)}-r I(r \mid n)$ for all $n \in \mathbb{Z}_{>0}$.
Proof of Theorem 7. The equality

$$
\rho_{n}^{(r)}=\frac{1}{n} \sum_{d \mid n} \phi\left(\frac{n}{d}\right) L_{d}^{(r)}
$$

where $\rho_{n}^{(r)}$ is the number of cyclic 0-1 sequences of length $n$ that do not contain $r$ consecutive 1's, has been proven in Zhang and Hadjicostas [26].

The first equality in (13) follows from Theorem 1, Corollary 6, and the fact that

$$
\begin{equation*}
\frac{r}{n} \sum_{d \mid n} \phi\left(\frac{n}{d}\right) I(r \mid d)=I(r \mid n) . \tag{25}
\end{equation*}
$$

We leave it to the reader to prove equation (25).
Proof of Corollary 9. When $1 \leq n \leq m-1$, we have $c_{A}^{L}(n)=c_{\mathbb{Z}}^{L}(n)=2^{n-1}$, which is the total number of linear compositions of $n$ (of any length) with parts in the set of positive integers. It then follows from equation (9) that

$$
g_{A}(n)=\sum_{s=1}^{n-1} s 2^{n-s-1}+n=2^{n}-1 .
$$

When $n=m$, we have

$$
g_{A}(m)=\sum_{i=1}^{m-1} s 2^{m-s-1}+0=2^{m}-m-1
$$

For $m+1 \leq n \leq r$, the equation

$$
g_{A}(n)=\sum_{\substack{i=1 \\ i \neq m}}^{n-1} g_{A}(n-i)+n
$$

follows immediately from equation (8).

When $n>r$, equation (8) implies

$$
\begin{aligned}
g_{A}(n)= & \sum_{s=n-r}^{n-1} g_{A}(s) I(n-s \in A)+\sum_{s=1}^{n-r-1} g_{A}(s) I(n-r-s \in A) \\
& +(n-r) I(n-r \in A)+r I(n \in A)
\end{aligned}
$$

because $x \in A$ if and only $x-r \in A$ for $x>r$. Thus, for $n>r$, by applying equation (8) again for $n-r$ rather than $n$, we get

$$
\begin{aligned}
g_{A}(n) & =\sum_{\substack{s=n-r+1 \\
s \neq n-m}}^{n-1} g_{A}(s)+2 g_{A}(n-r)+r I(n \in A) \\
& =\sum_{\substack{s=1 \\
s \neq m}}^{r-1} g_{A}(n-s)+2 g_{A}(n-r)+r I[n \not \equiv m(\bmod r)],
\end{aligned}
$$

and this completes the proof of the corollary.

## 4 Examples

In this section, we illustrate the results of the paper for the cases $m=0<r=2$ and $m=1<r=2$, i.e., when $A$ consists of the positive odd integers and the positive even integers, respectively. Instead of using the subscript $A$ for the quantities $c_{A}^{L}(n), g_{A}(n)$ and $c_{A}^{R}(n)$, we use the subscript ' 2,0 ' for the first case and the subscript ' 2,1 ' for the second case. Values of these three quantities for each of the two cases are given in Table 1 from $n=1$ to $n=20$.

The generating functions of the three quantities when $A$ is the set of all odd positive integers are

$$
\begin{aligned}
1+\sum_{n \geq 1} c_{2,0}^{L}(n) x^{n} & =\frac{1-x^{2}}{1-x-x^{2}}, \\
\sum_{n \geq 1} g_{2,0}(n) x^{n} & =\frac{x\left(x^{2}+1\right)}{\left(1-x-x^{2}\right)\left(1-x^{2}\right)}, \\
\sum_{n \geq 1} c_{2,0}^{R}(n) x^{n} & =\sum_{n \geq 1} \frac{\phi(n)}{n} \log \frac{1-x^{2 n}}{1-x^{n}-x^{2 n}} .
\end{aligned}
$$

The generating functions of the three quantities when $A$ is the set of all even positive

| $n$ | $c_{2,0}^{L}(n)$ | $c_{2,1}^{L}(n)$ | $g_{2,0}(n)$ | $g_{2,1}(n)$ | $c_{2,0}^{R}(n)$ | $c_{2,1}^{R}(n)$ |

Table 1: Evaluations of various sequences for the cases $m=0<r=2$ and $m=1<r=2$.
integers are

$$
\begin{aligned}
1+\sum_{n \geq 1} c_{2,1}^{L}(n) x^{n} & =\frac{1-x^{2}}{1-2 x^{2}}, \\
\sum_{n \geq 1} g_{2,1}(n) x^{n} & =\frac{2 x^{2}}{\left(1-2 x^{2}\right)\left(1-x^{2}\right)}, \\
\sum_{n \geq 1} c_{2,1}^{R}(n) x^{n} & =\sum_{n \geq 1} \frac{\phi(n)}{n} \log \frac{1-x^{2 n}}{1-2 x^{2 n}} .
\end{aligned}
$$

By using a symbolic computation package that has calculus and number theory capabilities, one can expand the above six generating functions around $x=0$ far enough in order to obtain the results in Table 1.

Alternatively, we can find recurrences for the first two quantities in each case. For the
first case:

$$
\begin{aligned}
& c_{2,0}^{L}(1)=c_{2,0}^{L}(2)=1, \\
& c_{2,0}^{L}(n)=c_{2,0}^{L}(n-1)+c_{2,0}^{L}(n-2) \quad \text { for } n>2 ; \\
& g_{2,0}(1)=1, \quad g_{2,0}(2)=1, \\
& g_{2,0}(n)=g_{2,0}(n-1)+g_{2,1}(n-2)+2 I(2 \nmid n) \quad \text { for } n>2 .
\end{aligned}
$$

Of course the sequence $\left(c_{2,0}^{L}(n): n \in \mathbb{Z}_{>0}\right)$ is the classical Fibonacci sequence, while the sequence ( $g_{2,0}(n): n \in \mathbb{Z}_{>0}$ ) satisfies

$$
g_{2,0}(n)=L_{n}^{(2)}-2 I(2 \mid n)=L_{n}^{(2)}-\left[1+(-1)^{n}\right] \quad \text { for all } n \in \mathbb{Z}_{>0}
$$

and it is given by A 001350 . These numbers are called "associate Mersenne numbers" by Haselgrove [10] in an article that he published in 1949 in the Cambridge University Mathematics Society magazine Eureka. (It is actually one of three sequences that he calls like that.) The sequence ( $c_{2,0}^{R}(n): n \in \mathbb{Z}_{n>0}$ ) can be calculated through equations (13) and it appears in A032189.

For the second case, using Theorem 8 and Corollary 9, we find

$$
\begin{aligned}
& c_{2,1}^{L}(1)=0, \quad c_{2,1}^{L}(2)=1 \\
& c_{2,1}^{L}(n)=2 c_{2,1}^{L}(n-2) \quad \text { for } n>2 \\
& g_{2,1}(1)=0, \quad g_{2,1}(2)=2 \\
& g_{2,1}(n)=2 g_{2,1}(n-2)+2 I(2 \mid n) \quad \text { for } n>2
\end{aligned}
$$

In this case, it is easy to prove that for all $n \geq 1$ :

$$
c_{2,1}^{L}(n)=2^{\frac{n}{2}-1} I(2 \mid n) \quad \text { and } \quad g_{2,1}(n)=\left(2^{\frac{n}{2}+1}-2\right) I(2 \mid n) .
$$

The sequence $\left(c_{2,1}^{R}(n): n \in \mathbb{Z}_{n>0}\right)$ can be calculated through equation (5). Obviously, $c_{2,1}^{R}(2 n-1)=0$ for $n \in \mathbb{Z}_{>0}$, while the sequence $\left(c_{2,1}^{R}(2 n): n \in \mathbb{Z}_{n>0}\right)$ appears in A008965.

## 5 Concluding remarks

The various $r$-step Lucas numbers $L_{n}^{(r)}$, defined by equations (11) and (12), have been studied extensively and satisfy various combinatorial identities involving binomial coefficients; e.g., see Charalambides [6]. When $A$ is the set of all positive integers that are not multiples of a positive integer $r$, we managed to express $c_{A}^{R}(n)$ in terms of $L_{n}^{(r)}$ through equation (13) in Theorem 7. It would be nice to find a similar elegant equality for the numbers $c_{A}^{R}(n)$ in terms of well-studied sequences of integers for the case

$$
A=\mathbb{Z}_{>0}-\left\{m+j r: j \in \mathbb{Z}_{>0}\right\}
$$

when $r, m \in \mathbb{Z}_{>0}$ with $1 \leq m<r$.
Finally, it would be nice to find a simple and elegant combinatorial argument to prove

$$
c_{A}^{R}(n)=-I(r \mid n)+\rho_{n}^{(r)}
$$

when $A=\mathbb{Z}_{>0}-\left\{r j: j \in \mathbb{Z}_{>0}\right\}$. Is there a 'quasi-bijection' between the number of cyclic compositions of $n$ that are not multiples of $r$ with the number of cyclic 0-1 sequences of length $n$ that do not contain $r$ consecutive 1s?

## 6 Acknowledgement

The author wishes to thank statistician Lingyun Zhang whose ideas and work have inspired this paper.
