# IRRATIONALITY MEASURES FOR CONTINUED FRACTIONS WITH ARITHMETIC FUNCTIONS 

Jaroslav Hančl and Kalle Leppälä

#### Abstract

Let $f(n)$ or the base- 2 logarithm of $f(n)$ be either $d(n)$ (the divisor function), $\sigma(n)$ (the divisor-sum function), $\varphi(n)$ (the Euler totient function), $\omega(n)$ (the number of distinct prime factors of $n$ ) or $\Omega(n)$ (the total number of prime factors of $n$ ). We present good lower bounds for $\left|\frac{M}{N}-\alpha\right|$ in terms of $N$, where $\alpha=[0 ; f(1), f(2), \ldots]$.

## 1. Introduction and notations

For $\alpha \in \mathbb{R}$ and $N \in \mathbb{Z}_{+}$denote $J_{\alpha}(N)=N\|N \alpha\|$, where $\|\cdot\|$ means the distance to the nearest integer. The function $J_{\alpha}(N)$ is connected to the rougher concept of the irrationality exponent $\mu(\alpha)$, the infimum of exponents $\mu$ such that $J(N) \leqslant N^{2-\mu}$ holds for infinitely many $N$. For almost all $\alpha$ we have $\mu(\alpha)=2$, although $\mu(\alpha)=1$ for rational numbers and $\mu(\alpha) \in(2, \infty]$ for a zero-measure subset of irrational numbers. For more information, see 1 for example. In all of our examples we have the usual $\mu(\alpha)=2$ but we go further by studying the more refined function $J_{\alpha}(N)$. For irrational $\alpha$ we are interested in finding lower bounds $J_{\alpha}(N) \geqslant f(N)$ for $N \geqslant N_{0}$. To emphasize that our results are in some sense sharp we also give bounds $J_{\alpha}(N) \leqslant g(N)$ holding for infinitely many $N$. Throughout the work, this kind of pair of bounds is denoted by

$$
J_{\alpha}(N) \in(f(N), g(N)\rangle
$$

Another short-hand notation used in the statement of Theorem [2.1] is to write

$$
L_{k}(N)=\underbrace{\log \log \cdots \log }_{k \text { times }} N .
$$

[^0]Because of the law of best approximations, the simple continued fraction expansion of $\alpha$ is ideal for bounding $J_{\alpha}(N)$. Recall that if $\alpha=\left[a_{0} ; a_{1}, \ldots\right]$ is the simple continued fraction expansion of the irrational number $\alpha$ and $p_{n} / q_{n}=\left[a_{0} ; a_{1}, \ldots, a_{n}\right]$ is the $n$-th convergent for each $n \in \mathbb{N}$, we have the recursion formulae

$$
\begin{gather*}
p_{0}=a_{0}, \quad q_{0}=1, \quad p_{1}=a_{1} a_{0}+1, \quad q_{1}=a_{1} \\
p_{n+2}=a_{n+2} p_{n+1}+p_{n}, \quad q_{n+2}=a_{n+2} q_{n+1}+q_{n} \tag{1.1}
\end{gather*}
$$

for $n \in \mathbb{N}$, and the estimates

$$
\begin{equation*}
\frac{1}{q_{n}^{2}\left(a_{n+1}+2\right)}<\left|a-\frac{p_{n}}{q_{n}}\right|<\frac{1}{q_{n}^{2} a_{n+1}} \tag{1.2}
\end{equation*}
$$

for $n \in \mathbb{N}$. We shall use the notation $[0 ; \overline{f(j)}]_{j=1}^{\infty}=[0 ; f(1), f(2), \ldots]$, where $f: \mathbb{Z}_{+} \rightarrow \mathbb{Z}_{+}$is a function. For more details on continued fractions please see the book of Hardy and Wright [6] for example.

The case where the asymptotic geometric mean of the sequence $\left\{a_{j}\right\}_{j=0}^{\infty}$ tends to infinity is easiest to deal with, although it is untypical in the metric sense. In that case the lowest behavior of the function $J_{\alpha}(N)$ is basically governed by the maximal order and the asymptotic geometric mean of the sequence $\left\{a_{j}\right\}_{j=0}^{\infty}$. In our examples we have chosen $a_{n}=f(n)$ or $a_{n}=2^{f(n)}$ with some arithmetic function $f(n)$, because maximal orders of arithmetic functions have been extensively studied by Landau, Ramanujan, Nicolas, etc. (see [2, 6, 7, 8, $\mathbf{9}$ for example). On the other hand, the behavior of the asymptotic geometric mean of arithmetic functions is generally not known. This is not a big problem however; as long as there is enough error in the maximal order of $f(n)$, it suffices to bound the asymptotic geometric mean by asymptotic arithmetic mean, which again is usually known (more typically called the average order of $f(n)$, see [6, 10] for example). And of course in the cases $a_{n}=2^{f(n)}$ the base-2 logarithm of the geometric mean of $a_{n}$ simply corresponds to the arithmetic mean of $f(n)$.

Finally we note that we have already introduced bounds like (2.2) as an example in our currently unpublished work [4. However, the result of (2.2) is slightly sharper and presented here for completeness.

## 2. Results

The following theorem contains our bounds in all of the ten examples. Note that the lower bounds are always asymptotically bigger than any negative power of $N$, implying that in each case the irrationality exponent is 2 .

ThEOREM 2.1. Let $d(n)$ be the number of positive divisors of $n$. Then

$$
\begin{equation*}
J_{[0 ; \overline{d(j)}]_{j=1}^{\infty}}(N) \in\left(2^{-\frac{L_{2}(N)\left(L_{3}^{2}(N)+L_{3}(N)+4.7624\right)}{L_{3}^{3}(N)}}, 2^{-\frac{L_{2}(N)}{L_{3}(N)-1+O\left(L_{4}(N) / L_{3}(N)\right)}}\right\rangle \tag{2.1}
\end{equation*}
$$

(2.2) $J_{\left[0 ; 2^{d(j)}\right]}^{j=1},{ }_{j}^{\infty}(N)$
where $N$ is big enough.
Let $\sigma(n)$ be the sum of positive divisors of $n$. Then

$$
\begin{align*}
& \quad J_{[0 ; \overline{\sigma(j)}]_{j=1}^{\infty}}(N) \in\left(\frac{L_{3}(N)\left(L_{2}(N)-L_{3}(N)\right)}{L_{1}(N)\left(e^{\gamma} L_{3}^{2}(N)+0.6483\right)}, \frac{L_{2}(N)(1+o(1))}{e^{\gamma} L_{1}(N) L_{3}(N)}\right\rangle,  \tag{2.3}\\
& J_{\left[0 ; 2^{\sigma \sigma(j)}\right]_{j=1}^{\infty}}(N) \\
& \in\left(2^{-\frac{2 \sqrt{3 L_{1}(N)}\left(e^{\gamma}\left(L_{3}(N)-L_{1}(2)\right) L_{3}(N)+0.6483\right)}{\pi \sqrt{L_{1}(2)} L_{3}(N)}}, 2^{-\frac{2 e^{\gamma}}{\pi}} \sqrt{\frac{3 L_{1}(N)}{L_{1}(2)}} L_{3}(N)(1+o(1))\right.
\end{align*},
$$

where $\gamma$ is the Euler-Mascheroni constant and $N$ is big enough.
Let $\varphi(n)$ be the number of positive integers less than and prime to $n$, denote

$$
A=\sum_{p \text { prime }} \frac{1}{p} \log \left(1+\frac{1}{p}\right)
$$

let $z(x)$ stand for the inverse of the function $y(x)=x \log x$, and define $z_{0}(x)=x$ and $z_{k+1}(x)=x / \log \left(z_{k}(x)\right)$ for each $k$ (see [3]). Then

$$
\begin{align*}
& J_{[0 ; \overline{\varphi(j)}]_{j=1}^{\infty}(N)}  \tag{2.5}\\
& \in\left(\frac{2 L_{1}(N) L_{1}\left(z\left(e^{A-1} L_{1}(N)\right)\right)+L_{2}^{2}(N)-2 L_{1}(N) L_{3}(N)+O\left(L_{2}(N)\right)}{2 L_{1}^{2}(N)+4 L_{1}(N)},\right. \\
& \left.\frac{2 L_{1}(N) L_{1}\left(z\left(e^{A-1} L_{1}(N)\right)\right)+L_{2}^{2}(N)+O\left(L_{2}(N)\right)}{2 L_{1}^{2}(N)}\right\rangle
\end{align*}
$$

or if one prefers the use of elementary functions only then one can replace $L_{1}\left(z\left(e^{A-1} L_{1}(N)\right)\right)$ by $L_{1}\left(z_{k}\left(e^{A-1} L_{1}(N)\right)\right)+O\left(L_{3}(N) / L_{2}^{k}(N)\right)$ for any $k$, and

$$
\begin{align*}
& J_{\left[0 ; 2^{\varphi(j)}\right] \infty}(N)  \tag{2.6}\\
& \quad \in\left(2^{-\pi \sqrt{\frac{L_{1}(N)}{3 \log 2}}+O\left(L_{2}^{2 / 3}(N) L_{3}^{3 / 4}(N)\right)}, 2^{-\pi \sqrt{\frac{L_{1}(N)}{3 \log 2}}+O\left(L_{2}^{2 / 3}(N) L_{3}^{3 / 4}(N)\right)}\right\rangle
\end{align*}
$$

Let $\omega(n)$ be the number of different prime factors of $n$, counted without multiplicities. Then

$$
\begin{align*}
& J_{[0 ; \overline{\omega(j)]}]_{j=1}^{\infty}}(N)  \tag{2.7}\\
& \quad \in\left(\frac{L_{3}^{3}(N)}{L_{2}(N)\left(L_{3}^{2}(N)+L_{3}(N)+2.89727\right)}, \frac{L_{3}(N)-1+O\left(\frac{L_{4}(N)}{L_{3}(N)}\right)}{L_{2}(N)}\right\rangle,
\end{align*}
$$

$$
\begin{align*}
& J_{\left[0 ; 2^{\omega(j)}\right]_{j=1}^{\infty}}(N)  \tag{2.8}\\
& \quad \in\left(2^{-\frac{L_{2}(N)\left(L_{3}^{2}(N)+L_{3}(N)+2.89727\right)}{L_{3}^{3}(N)}}, 2^{-\frac{L_{2}(N)}{L_{3}(N)-1+O\left(L_{4}(N) / L_{3}(N)\right)}}\right\rangle
\end{align*}
$$

where $N$ is big enough.
Let $\Omega(n)$ be the number of different prime factors of $n$, counted with multiplicities, and denote

$$
B=1-\log \log 2+\int_{2}^{\infty} \frac{\sum_{p \leqslant t} \frac{1}{p} \log p-\log t d t}{t(\log t)^{2}}+\sum_{p \text { prime }} \frac{1}{p(p-1)} .
$$

Then

$$
\begin{align*}
& J_{[0 ; \overline{\Omega(j)]}]_{j=1}^{\infty}}(N)  \tag{2.9}\\
& \quad \in\left(\frac{L_{1}(2)}{L_{2}(N)-L_{5}(N)+2 L_{1}(2)+o(1)}, \frac{L_{1}(2)}{L_{2}(N)-L_{5}(N)+o\left(1 / L_{4}(N)\right)}\right\rangle \\
& J_{\left[0 ; 2^{\Omega(j)}\right]_{j=1}^{\infty}}(N) \in\left(\frac{L_{1}(2)\left(L_{3}(N)+B+o(1)\right)}{L_{1}(N)}, \frac{L_{1}(2)\left(L_{3}(N)+B+o(1)\right)}{L_{1}(N)}\right\rangle . \tag{2.10}
\end{align*}
$$

Proof of Equation (2.1). The recursive formula (1.1) gives us

$$
q_{n}=a_{n} q_{n-1}\left(1+\frac{q_{n-2}}{a_{n} q_{n-1}}\right)=\cdots=\prod_{j=1}^{n} a_{j} \prod_{j=1}^{n-1}\left(1+\frac{q_{j-1}}{a_{j+1} q_{j}}\right)=e^{O(n)} \prod_{j=1}^{n} a_{j}
$$

since $1+q_{j-1} /\left(a_{j+1} q_{j}\right) \in(1,2)$ for all $j$. By using the asymptotic arithmetic mean

$$
\begin{equation*}
\frac{1}{n} \sum_{j=1}^{n} d(j)=\log n+O(1) \tag{2.11}
\end{equation*}
$$

(Theorem 320 on page 347 of [6]) and the arithmetic-geometric inequality we get an upper bound $\log q_{n} \leqslant n \log \log n+O(n)$. On the other hand, the recursive formula (1.1) implies a trivial lower bound $\log q_{n} \geqslant b n$ with some positive constant $b$. Now we can solve $n$ from those inequalities to get

$$
\begin{aligned}
n & \geqslant \frac{\log q_{n}}{\log \log n+O(1)} \geqslant \frac{\log q_{n}}{\log \log \left(\frac{1}{b} \log q_{n}\right)+O(1)}=\frac{\log q_{n}}{\log \left(\log \log q_{n}-\log b\right)+O(1)} \\
& =\frac{\log q_{n}}{\log \log \log q_{n}+O\left(1 / \log \log q_{n}\right)+O(1)}=\frac{\log q_{n}}{\log \log \log q_{n}+O(1)}
\end{aligned}
$$

and $n \leqslant \log q_{n} / b$.
To show that the lower bound of the claim always holds we use a result

$$
\begin{equation*}
d(n) \leqslant 2^{\frac{\log n}{\log \log n}\left(1+\frac{1}{\log \log n}+\frac{4.7623 . \ldots}{(\log \log n)^{2}}\right)} \tag{2.12}
\end{equation*}
$$

of Robin (Proposition 8 in 8 with the constant rounded up to 4.7624 ; the fact that the constant is in fact strictly smaller is implicitly in $\mathbf{9}$ ) and the left inequality in (1.2), and we simplify this. Note that rounding the constant $4.7623 \ldots$ up to 4.7634
causes an error big enough to make many other terms, including the ones with $b$, negligible.

To show that the upper bound of the claim holds infinitely often we use a slightly weaker estimate. It is easy to show with the estimate $p_{n} \sim n \log n$ of the $n$-th prime number (Theorem 8 on page 12 of $[\mathbf{6}$ ) and Abel's partial summation formula

$$
\begin{equation*}
\sum_{j=1}^{n} a_{j} b_{j}=b_{n} \sum_{j=1}^{n} a_{j}-\sum_{j=1}^{n-1}\left(b_{j+1}-b_{j}\right) \sum_{i=1}^{j} a_{i}, \tag{2.13}
\end{equation*}
$$

that when $n$ is a product of the first primes we have

$$
\begin{equation*}
d(n)=2^{\frac{\log n}{\log \log n-1+O(\log \log \log n / \log \log n)}} . \tag{2.14}
\end{equation*}
$$

The result follows after using the right inequality of (1.2) and simplifying.
Proof of Equation (2.2). From the asymptotic arithmetic mean (2.11) we deduce

$$
\frac{\log q_{n}}{\log 2}=n \log n+O(n)=n \log n+O(n \log \log n)
$$

Because of the error in bounds (2.12) and (2.14), making our error bigger like this will not matter, but instead simplifies things. Solving for $n$ gives

$$
n=\frac{\log q_{n}}{\log 2 \log \log q_{n}+O\left(\log \log \log q_{n}\right)},
$$

and after simplifying, the claims follow from estimations (2.12), (2.14) and (1.2).

Proof of Equation (2.3). This time we bound the asymptotic geometric mean by the asymptotic arithmetic mean

$$
\begin{equation*}
\frac{1}{n} \sum_{j=1}^{n} \sigma(j)=\frac{\pi^{2}}{12} n+O(\log n) \tag{2.15}
\end{equation*}
$$

(Theorem 324 on page 351 of [6]) from above, and by the trivial estimate $\sigma(j) \geqslant j+1$ together with Stirling's formula from below to show that $\log q_{n}=n \log n+O(n)$. Solving for $n$ yields

$$
n=\frac{\log q_{n}}{\log \log q_{n}-\log \log \log q_{n}+O(1)} .
$$

To verify our claim on the lower bound we use the estimate

$$
\begin{equation*}
\sigma(n) \leqslant n\left(e^{\gamma} \log \log n+\frac{0.6482 \ldots}{\log \log n}\right) \tag{2.16}
\end{equation*}
$$

of Nicolas (Proposition 11 in $\mathbf{8}$ ), where $\gamma$ is the Euler-Mascheroni constant, and inequality (1.2).
For the upper bound we use Grönwall's theorem

$$
\begin{equation*}
\limsup _{n \rightarrow \infty} \frac{\sigma(n)}{n \log \log n}=e^{\gamma} \tag{2.17}
\end{equation*}
$$

(equation (25) in [2]), implying that $\sigma(n)=e^{\gamma} n \log \log n(1+o(1))$ for infinitely many values of $n$, and inequality (1.2).

Proof of Equation (2.4). Now the asymptotic arithmetic mean (2.15) directly gives us the estimate

$$
\log q_{n}=\frac{\pi^{2} \log 2}{12} n^{2}+O(n \log n)
$$

Solving for $n$ yields

$$
n=\frac{2}{\pi} \sqrt{\frac{3 \log q_{n}}{\log 2}}+O\left(\log \log q_{n}\right)
$$

After simplifying, the claims follow from estimations (2.16), (2.17) and (1.2) again.

Proof of Equation (2.5). We happen to know exactly how the function $\varphi(n)$ behaves at its biggest. Still we are allowed to have some slack in the estimates of the convergents because of the difficulty of solving $n$ in terms of $q_{n}$.

We write

$$
\prod_{j=1}^{n} \varphi(j)=\prod_{j=1}^{n} j \prod_{\substack{p \text { prime } \\ p \mid j}}\left(1-\frac{1}{p}\right)=n!\prod_{\substack{p \text { prime } \\ p \leqslant n}}\left(1-\frac{1}{p}\right)^{\lfloor n / p\rfloor} .
$$

Let us deal with the product over the primes first. By using the prime number theorem (Theorem 6 on page 10 of [6]) and partial integration, we see that

$$
\sum_{\substack{p \text { prime } \\ p \leqslant n}} \frac{1}{p} \log \left(1-\frac{1}{p}\right)=A+O\left(\frac{1}{n \log n}\right)
$$

where

$$
A=\sum_{p \text { prime }} \frac{1}{p} \log \left(1-\frac{1}{p}\right)
$$

is a known (negative) constant. So estimating $\lfloor n / p\rfloor \leqslant n / p$ gives

$$
\begin{equation*}
\log \left(\prod_{\substack{p \text { prime } \\ p \leqslant n}}\left(1-\frac{1}{p}\right)^{\lfloor n / p\rfloor}\right) \geqslant A n+O\left(\frac{1}{\log n}\right) \tag{2.18}
\end{equation*}
$$

On the other hand, by Mertens's theorem

$$
\prod_{\substack{p \text { prime } \\ p \leqslant n}}\left(1-\frac{1}{p}\right)=\frac{1+o(1)}{e^{\gamma} \log n}
$$

(Theorem on 429 on page 466 of [ $\mathbf{6}$ ), where $\gamma$ is the Euler-Mascheroni constant, estimating $\lfloor n / p\rfloor \geqslant n / p-1$ gives

$$
\begin{equation*}
\log \left(\prod_{\substack{p \text { prime } \\ p \leqslant n}}\left(1-\frac{1}{p}\right)^{\lfloor n / p\rfloor}\right) \leqslant A n+\log \log n+\gamma+o(1) . \tag{2.19}
\end{equation*}
$$

Next note that by recursive formula (1.1) and Landau's theorem

$$
\liminf _{n \rightarrow \infty} \frac{\varphi(n) \log \log n}{n}=\frac{1}{e^{\gamma}}
$$

(pages 217-219 of [7]), where $\gamma$ is the Euler-Mascheroni constant again, we see

$$
\prod_{j=1}^{n-1}\left(1+\frac{q_{j-1}}{\varphi(j+1) q_{j}}\right)=O(1)
$$

as a beginning of a converging product. Finally we use Stirling's formula and bounds (2.18) and (2.19) to get

$$
\begin{aligned}
& \log q_{n} \leqslant n \log n+(A-1) n+\frac{1}{2} \log (2 \pi n)+\log \log n+O(1) \\
& \log q_{n} \geqslant n \log n+(A-1) n+\frac{1}{2} \log (2 \pi n)+O(1)
\end{aligned}
$$

In any case we have at least

$$
n=\frac{\log q_{n}}{\log n+A-1+O(1 / n \cdot \log n)}
$$

which is equivalent to

$$
e^{A-1} n \log \left(e^{A-1} n\right)=e^{A-1} \log q_{n}+O(\log n)
$$

Now we apply the function $z(x)$ (the inverse of $x \log x)$ and the logarithm function to both sides of the equation to get

$$
\log n+A-1=\log z\left(e^{A-1} \log q_{n}+O(\log n)\right)
$$

The mean-value theorem implies

$$
\begin{aligned}
\log n+A-1 & =\log z\left(e^{A-1} \log q_{n}+O(\log n)\right) \\
& =\log \left(z\left(e^{A-1} \log q_{n}\right)+O\left(\frac{\log n}{\log z\left(\log q_{n}\right)}\right)\right) \\
& =\log z\left(e^{A-1} \log q_{n}\right)+O\left(\frac{\log n}{\log q_{n}}\right)
\end{aligned}
$$

Using this we can solve $n$ :

$$
\begin{aligned}
& n \geqslant \frac{\log q_{n}}{\log z\left(e^{A-1} \log q_{n}\right)+\frac{\left(\log \log q_{n}\right)^{2}}{2 \log q_{n}}+O\left(\frac{\log \log q_{n}}{\log q_{n}}\right)} \\
& n \leqslant \frac{\log q_{n}}{\log z\left(e^{A-1} \log q_{n}\right)+\frac{\left(\log \log q_{n}\right)^{2}}{2 \log q_{n}}-\log \log \log q_{n}+O\left(\frac{\log \log q_{n}}{\log q_{n}}\right)} .
\end{aligned}
$$

Now the claims follow from using (1.2), since $\varphi(n) \leqslant n-1$ with equality whenever $n$ is a prime.

We can also derive bounds that use only elementary functions but have bigger error. By using the fact that $\log z\left(e^{A-1} \log q_{n}\right)$ as well as $\log z_{k}\left(e^{A-1} \log q_{n}\right)$ for any
$k$ is $O\left(\log \log q_{n}\right)$, we see that

$$
\begin{aligned}
\log z\left(e^{A-1} \log q_{n}\right) & =\log \left(\frac{e^{A-1} \log q_{n}}{\log z\left(e^{A-1} \log q_{n}\right)}\right) \\
& =A-1+\log \log q_{n}+O\left(\log \log \log q_{n}\right) \\
& =\log z_{0}\left(e^{A-1} \log q_{n}\right)+O\left(\log \log \log q_{n}\right)
\end{aligned}
$$

and inductively

$$
\begin{aligned}
& \log z\left(e^{A-1} \log q_{n}\right)=\log \left(\frac{e^{A-1} \log q_{n}}{\log z\left(e^{A-1} \log q_{n}\right)}\right) \\
& \quad=\log \left(\frac{e^{A-1} \log q_{n}}{\log z_{k-1}\left(e^{A-1} \log q_{n}\right)+O\left(\frac{\log \log \log q_{n}}{\left(\log \log q_{n}\right)^{k-1}}\right)}\right) \\
& \quad=A-1+\log \log q_{n}-\log \log z_{k-1}\left(e^{A-1} \log q_{n}\right)+O\left(\frac{\log \log \log q_{n}}{\left(\log \log q_{n}\right)^{k}}\right) \\
& \quad=\log z_{k}\left(e^{A-1} \log q_{n}\right)+O\left(\frac{\log \log \log q_{n}}{\left(\log \log q_{n}\right)^{k}}\right)
\end{aligned}
$$

for any $k$.
Proof of Equation (2.6). From the asymptotic arithmetic mean

$$
\frac{1}{n} \sum_{j=1}^{n} \varphi(j)=\frac{3}{\pi^{2}} n+O\left((\log n)^{\frac{2}{3}}(\log \log n)^{\frac{3}{4}}\right)
$$

(see $1 \mathbf{1 0}$ ) we get

$$
\log q_{n}=\frac{3 \log 2}{\pi^{2}} n^{2}+O\left(n(\log n)^{\frac{2}{3}}(\log \log n)^{\frac{3}{4}}\right)
$$

Solving for $n$ yields

$$
n=\pi \sqrt{\frac{\log q_{n}}{3 \log 2}}+O\left(\left(\log \log q_{n}\right)^{\frac{2}{3}}\left(\log \log \log q_{n}\right)^{\frac{3}{4}}\right)
$$

and so the claim follows by using (1.2), since $\varphi(n) \leqslant n-1$, with equality whenever $n$ is a prime.

Proof of Equation (2.7). The asymptotic arithmetic mean

$$
\begin{equation*}
\frac{1}{n} \sum_{j=1}^{n} \omega(j)=\log \log n+O(1) \tag{2.20}
\end{equation*}
$$

(Theorem 430 on page 472 of [6]) implies $\log q_{n} \leqslant n \log \log \log n+O(n)$, and trivially $\log q_{n} \geqslant b n$ with some positive constant $b$. Solving for $n$ gives

$$
\frac{\log q_{n}}{\log \log \log \log q_{n}+O(1)} \leqslant n \leqslant \frac{\log q_{n}}{b} .
$$

To see that the lower bound of the claim always holds we use a result

$$
\begin{equation*}
\omega(n) \leqslant \frac{\log n}{\log \log n}\left(1+\frac{1}{\log \log n}+\frac{2.89726 \ldots}{(\log \log n)^{2}}\right) \tag{2.21}
\end{equation*}
$$

of Nicolas (Proposition 5 in $[\mathbf{8}$ ) and inequality (1.2). For the upper bound we use the fact that when $n$ is a product of first primes, we have

$$
\begin{equation*}
\omega(n)=\frac{\log n}{\log \log n-1+O\left(\frac{\log \log \log n}{\log \log n}\right)} \tag{2.22}
\end{equation*}
$$

The claims follow from this and (1.2).
Proof of Equation (2.8). Now the asymptotic arithmetic mean (2.20) directly gives us the estimate

$$
\frac{\log q_{n}}{\log 2}=n \log \log n+O(n)
$$

from which we solve

$$
n=\frac{\log q_{n}}{\log 2 \log \log \log q_{n}+O(1)}
$$

The claims follow from inequalities (2.21), (2.22) and (1.2).
Proof of Equation (2.9). Again we want to be sharper than usual because we know the exact worst-case behavior of $\Omega(n)$. We shall use a theorem of Hardy and Ramanujan (Theorem $\mathrm{C}^{\prime}$ in [5]), stating that whenever $f(n)$ is a function tending to infinity, we have

$$
\begin{equation*}
\log \log n-f(n) \sqrt{\log \log n} \leqslant \Omega(n) \leqslant \log \log n+f(n) \sqrt{\log \log n} \tag{2.23}
\end{equation*}
$$

for almost all $n$. In particular, by choosing $f(n)=(\log \log n)^{\frac{1}{4}}$ and using Abel's summation formula (2.13) we get an estimate

$$
\begin{equation*}
\prod_{j=1}^{n-1}\left(1+\frac{q_{j-1}}{a_{j+1} q_{j}}\right) \leqslant \prod_{j=1}^{n(1+o(1))}\left(1+\frac{1}{\log \log j-(\log \log j)^{\frac{3}{4}}}\right) e^{o(n)}=e^{o(n)} \tag{2.24}
\end{equation*}
$$

Now this and the asymptotic arithmetic mean

$$
\begin{equation*}
\frac{1}{n} \sum_{j=1}^{n} \Omega(j)=\log \log n+B+o(1) \tag{2.25}
\end{equation*}
$$

where

$$
B=1-\log \log 2+\int_{2}^{\infty} \frac{\sum_{p \leqslant t} \frac{1}{p} \log p-\log t d t}{t(\log t)^{2}}+\sum_{p \text { prime }} \frac{1}{p(p-1)}
$$

is a known constant (Theorem 430 on page 472 of [6]) imply

$$
\log q_{n} \leqslant n \log \log \log n+o(n)
$$

As a lower bound we only get, by using (2.23), that

$$
\log q_{n} \geqslant n \log \log \log n(1+o(1)) .
$$

Solving for $n$ yields

$$
\frac{\log q_{n}}{\log \log \log \log q_{n}+o(1)} \leqslant n \leqslant \frac{\log q_{n}}{\log \log \log \log q_{n}(1+o(1))} .
$$

Because obviously $\Omega(n) \leqslant \log n / \log 2$, with equality whenever $n$ is a power of 2 , both claims now follow by using (1.2).

Proof of Equation (2.10). We may use the upper bound (2.24) and the asymptotic arithmetic mean (2.25) to get the estimate

$$
\frac{\log q_{n}}{\log 2}=n \log \log n+B n+o(n)
$$

Now

$$
n=\frac{\log q_{n}}{\log 2\left(\log \log \log q_{n}+B+o(1)\right)},
$$

and so the claim follows by using (1.2), since $\Omega(n) \leqslant \log n / \log 2$, with equality whenever $n$ is a power of 2 .
