# Framed holonomic knots 

Tobias Ekhol m<br>Maxime Wolff

#### Abstract

A holonomic knot is a knot in 3 -space which arises as the 2 -jet extension of a smooth function on the circle. A holonomic knot associated to a generic function is naturally framed by the blackboard framing of the knot diagram associated to the 1-jet extension of the function. There are two classical invariants of framed knot diagrams: the Whitney index (rotation number) W and the seff linking number S .

For a framed holonomic knot we show that W is bounded above by the negative of the braid index of the knot, and that the sum of W and jSj is bounded by the negative of the Euler characteristic of any Seifert surface of the knot.

The invariant S restricted to framed holonomic knots with $\mathrm{W}=\mathrm{m}$, is proved to split into $n$, where $n$ is the largest natural number with $n \frac{j m j}{2}$, integer invariants. Using this, the framed holonomic isotopy classi cation of framed holonomic knots is shown to be more re ned than the regular isotopy dassi cation of their diagrams.

## 1 Introduction

## 1.A Holonomic knots and framing

Let $\mathrm{f}: \mathrm{S}^{1}!\mathbb{R}$ be a smooth function. The holonomic plane curve and holonomic space curve associated to $f$ are the 1 -jet extension c and the 2 -jet extension C of f , respectively. That is, $\mathrm{c}(\mathrm{t})=(\mathrm{f}(\mathrm{t}) ; \mathrm{f}(\mathrm{t}))$, and $\mathrm{C}(\mathrm{t})=$ $\left(f(t) ; \mathrm{f}^{9}(\mathrm{t}) ; \mathrm{f}^{\oplus}(\mathrm{t})\right.$ ) where $\mathrm{t} 2 \mathrm{~S}^{1}$, and where ( $\left.\mathrm{x}_{0} ; \mathrm{x}_{1}\right)$ and ( $\mathrm{x}_{0} ; \mathrm{x}_{1} ; \mathrm{x}_{2}$ ) are linear coordinates on $\mathbb{R}^{2}$ and $\mathbb{R}^{3}$, respectively.
A holonomic knot is a holonomic space curve which is an embedding. A framed holonomic knot is a holonomic knot with associated holonomic plane curve
which is an immersion. If $f$ is a function giving rise to a framed holonomic knot $C$ then ( $\left.\mathrm{f}^{9}(\mathrm{t}) ; \mathrm{f}^{\mathscr{C}}(\mathrm{t})\right) \in 0$, for all $\mathrm{t} 2 \mathrm{~S}^{1}$, and we consider the constant vector eld $@_{2}$ as a normal vector eld along C.

In the space of smooth functions on the circle, the functions with associated holonomic space curve being a (framed) holonomic knot form an open and dense subset. A (framed) holonomic isotopy is a continuous 1-parameter family of (framed) holonomic knots, or equivalently a continuous path in the space of (framed) holonomic knots.

Vassiliev [5] introduced holonomic knots and proved that any knot class (topological isotopy class of knots) has a holonomic representative and also that there exists a natural isomorphism from nite type invariants of topological knots to nite type invariants of holonomic knots.

Birman and Wrinkle [2] showed that two holonomic knots which are topologically isotopic are in fact holonomically isotopic. From a combinatorial point of view this means that the hol onomic isotopy classi cation of hol onomic knots is identical to the isotopy classi cation of their diagrams. (A knot diagram is the image of a generic projection of a knot to a plane in $\mathbb{R}^{3}$, decorated with over and under crossing information at its double points. An isotopy of a knot digram is de ned to be a sequence of planar isotopies and Reidemeister moves, see e.g. Kau man [3].)

## 1.B Whitney index and self linking number

Following Kau man [3], we say that two knot diagrams which can be deformed into each other by a sequence of planar isotopies and, second- and third Reidemeister moves (i.e the moves the projections of which are self-tangency- and triple point instances) are called regularly isotopic. There are two simple invariants of regular isotopy:
Fix an orientation of the ambient $\mathbb{R}^{3}$. This orientation together with a xed orientation of the projection direction associated to the knot diagram induce an orientation on the projection plane. The Whitney index W is the tangential degree of the knot diagram viewed as an oriented regular plane curve in the projection plane. The self linking number $S$ is the linking number of a knot $K$ which projects to the diagram and a copy of $K$ shifted slightly in the projection direction, computed using the xed orientation of the ambient $\mathbb{R}^{3}$.

TheWhitney formula [6] expresses the Whitney index of a generic regular plane curve as follows. Let $q$ be a point on $C$ such that $C$ lies on one side of the
tangent line of $C$ at $q$. Let $(q)=1$ denote the winding number of $C$ with respect to $q^{0}$, where $q^{0}$ is the point $q$ shifted slightly into the half plane which contains the curve The orientation of $C$ and the point q induces an ordering of the premages of a self intersection point $p$ of $C$. Let $p=1$ be the sign of the orientation of the plane induced from the tangent vectors of the ordered branches of $C$ intersecting at $p$. Then

$$
W(C)=-{ }_{p}^{X}(p)+(q):
$$

The seff linking number is the sum of the crossing signs over all crossings of the diagram. Hence $\mathrm{W}+\mathrm{S}$ is an odd integer.

In our study of framed holonomic knots we use the orientation $\mathrm{dx}_{0} \wedge \mathrm{dx}_{1} \wedge \mathrm{dx}_{2}>$ 0 and project along the $x_{2}$-axis oriented by $\mathrm{dx}_{2}>0$ to de ne W and S for framed holonomic knots. The ranges of these invariants are easily found:

Proposition 1.1 Let C be a framed holonomic knot. Then $\mathrm{W}(\mathrm{C})<0$, and if $\mathrm{W}(\mathrm{C})=-1$ then $\mathrm{S}(\mathrm{C})=0$ and C represents the unknot. Let $\mathrm{m} \quad-2$ and $n 2 \mathbb{Z}$ be such that $m+n$ is odd. Then there exists a framed holonomic knot with $W(C)=m$ and $S(C)=n$.

Proposition 1.1 is proved in Subsection 2.A.
It is more interesting to consider the ranges of W and S restricted to diagrams representing a xed knot class $K$. It is easy to see that for any integers $m$ and $n$ such that $m+n$ is odd there exists a diagram $D$ which represents $K$ with $W(D)=m$ and $S(D)=n$. If the domains of $W$ and $S$ are restricted further to framed holonomic knots which represent K the situation changes drastically.

Theorem 1.2 Let C be a framed holonomic knot representing the knot class $K$. Then

$$
\begin{equation*}
\text { W(C) } \quad \text { - braid(K ); } \tag{1.1}
\end{equation*}
$$

where braid $(K)$ is the braid index of $K$, and

$$
\begin{equation*}
W(C)+j S(C) j \quad 2 g(K)-1 ; \tag{1.2}
\end{equation*}
$$

where $g(K)$ denotes the genus of $K$.
Theorem 1.2 is proved in Subsection 3.C. The proof of (1.2) uses the Bennequin inequality [1] from the theory of Legendrian knots: if ( $x ; y ; z$ ) are coordinates on $\mathbb{R}^{3}$ and $\mathbb{R}^{3}$ is oriented by $\mathrm{dx}{ }^{\wedge} \mathrm{dy}{ }^{\wedge} \mathrm{dz}>0$ then this inequality asserts that
for the xy-diagram $\Gamma_{\mathbb{C}}$ of a knot $\Gamma$ which is everywhere tangent to the edd of hyperplanes $\operatorname{ker}(\mathrm{dz}-\mathrm{ydx})$ and which represents the knot class K

$$
\begin{equation*}
S\left(\Gamma_{\mathbb{C}}\right)+j W\left(\Gamma_{\mathbb{C}}\right) j \quad 2 g(K)-1: \tag{1.3}
\end{equation*}
$$

It is a curious fact that the roles of $S$ and $W$ in (1.2) and (1.3) are reversed.

## 1.C New invariants of framed holonomic knots

Trace [4] showed that two knot diagrams D and $\mathrm{D}^{0}$ are regularly isotopic if and only if they represent the sameknot class, $\mathrm{W}(\mathrm{D})=\mathrm{W}(\mathrm{D} 9$, and $\mathrm{S}(\mathrm{D})=\mathrm{S}(\mathrm{D} 9$. The classi cation problem for framed holonomic knots resembles the problem of classifying knot diagrams up to regular isotopy in the following way. Regular isotopy is knot diagram isotopy without rst Reidemester moves (the move which projects to a cusp-instance) and framed holonomic isotopy is holonomic isotopy without the holonomic rst Reidemeister move, see Figure 2.

Theorem 1.3 On the space of framed holonomic knots with Whitney index equal to $m$, the invariant $S$ splits. More precisely, to each framed holonomic knot $C$ with $\mathrm{W}(\mathrm{C})=\mathrm{m}$ there is associated n , where n is the largest integer with $n \frac{\text { jmj }}{2}$, integers $S_{1}(C) ;::: ; S_{n}(C)$, which are invariant under framed holonomic isotopy. Moreover,

$$
\begin{equation*}
S(C)={ }_{j=1}^{X^{n}} S_{j}(C): \tag{1.4}
\end{equation*}
$$

The invariants $S_{j}$ are de ned in De nition 4.1 and Theorem 1.3 is proved in Subsection 4.A.

In Section 5 we give examples of framed holonomic knots representing the same knot class, with the same W and S but which are distinguished up to framed holonomic isotopy by the invariants $\mathrm{S}_{\mathrm{j}}$. This shows that the classi cation of framed hol onomic knots up to framed holonomic isotopy is morere ned than the regular isotopy classi cation of their diagrams. This result should be compared to the result of Birman and Wrinkle mentioned in Subsection 1.A.

## 1.D Holonomic regular homotopy

A holonomic regular homotopy is a continuous 1-parameter family of regular holonomic plane curves.

Proposition 1.4 Two regular holonomic plane curves are holonomically regularly homotopic if and only if they have the same Whitney index.

Proposition 1.4 is proved in Subsection 2.B. If the holonomic requirements in Proposition 1.4 are removed one obtains the dassical Whitney-Graustein theorem [6]. The proof we present is independent of this theorem.

## 2 Diagrams of holonomic knots and Reidemeister moves

For the readers convenience, basic facts on the geometry of diagrams of holonomic knots are presented. For proofs of these facts, see [5], Proposition 1.
Let $f: S^{1}!\mathbb{R}$ be a generic function. Then the $x_{0} x_{1}$-diagram $c$ of the framed holonomic knot $C$ associated to $f$ has the following properties:

P1 c is a regular curve and if p is a point on c in the upper (lower) half plane and v is the unit tangent of c at p then $\mathrm{hv} ; @_{0} \mathrm{i}>0\left(\mathrm{hv} ; Q_{0} \mathrm{i}<0\right)$, where $h ; i$ denotes the standard inner product on $\mathbb{R}^{2}$.

P2 c meets the $x_{0}$-axis at right angles at a nite number of points corre sponding to the local extrema of $f$. The curvature of $c$ at such a point $p$ does not vanish and if $p$ corresponds to maximum (minimum) of $f$ the unit tangent of $c$ at $p$ equals $-@_{1}\left(@_{1}\right)$.
P3 The only self intersection points of $c$ are transverse double points which lie in the region $f\left(x_{0} ; x_{1}\right): x_{1} \in 0 g$. The crossing number of a double point in the upper (lower) half plane is negative (positive) with respect to the orientation $\mathrm{dx}_{0} \wedge \mathrm{dx}_{1} \wedge \mathrm{dx} x_{2}>0$.

In generic 1-parameter families of framed holonomic knots the diagram changes by planar isotopy which preserve properties $\mathbf{P 1}\{\mathbf{3}$ above except for a nite number of instances where one of the bifurcations in Figure 1 occur. Note that the $\Omega_{2}$-moves always occur on the $\mathrm{x}_{0}$-axis. The signs on the $\Omega_{2}$-moves refer to the signs of the product of the second derivatives at the extrema meeting at the self-tangency moment of the function de ning the holonomic knot. The $\Omega_{3}$-move depicted occurs either in the upper- or lower half plane.

If the word framed above is omitted the corresponding result is: In generic 1parameter families of holonomic knots the diagram changes by planar isotopy which preserve properties $\mathbf{P} \mathbf{1}\{\mathbf{3}$ above except for a nite number of instances where one of the bifurcations in Figures 1 or 2 occur. Thesigns of the $\Omega_{1}$-moves

Figure 1: Framed holonomic Redemeister moves

Figure 2: Holonomic versions of the rst Reidemeister move
in Figure 2 refer to the sign of $x_{1}$ in the half plane where a double point is born or vanishes.

If we further omit the condition that the holonomic curve be an embedding then

Algebraic \& Geometric Topology, Volume 2 (2002)
the list of diagram-bifurcations would be further extended and include also the move in Figure 3 (which might dhange the knot class of the holonomic curve). The signs on the $\Omega_{0}$-moves in Figure 3 refer to the half plane where double

Figure 3: Framed holonomic crossing move
points are born or vanish.

## 2.A Proof of Proposition 1.1

Let $\left(x_{0} ; x_{1} ; x_{2}\right)=\left(x_{0} ; x_{1}\right)$. Let $f$ be a generic function on the circle, let $C$ be its associated holonomic knot, and let $c=(C)$. To see that $\mathrm{W}(\mathrm{C})<0$ compute the Whitney index by looking at points p on c where the unit tangent equals $@_{1}$. These correspond to minima of $f$ and all of them contribute -1 to W . The second statement is immediate

To create a holonomic knot $C$ with $\mathrm{W}(\mathrm{C})=\mathrm{m}, \mathrm{m} \quad-2$ and $\mathrm{S}(\mathrm{C})=\mathrm{n}$, start from the holonomic unknot diagram (which is just the unit circle). If $n 0$ ( $\mathrm{n}<0$ ) apply $\Omega_{1}^{+}\left(\Omega_{1}^{-}\right) \mathrm{m}-1$ times in such a way that the resulting diagram contains $\mathrm{m}-1$ consecutive loops along the $\mathrm{x}_{0}$-axis. The resulting holonomic knot has $W=m$ and $S=-(m-1)$ if $n \quad 0(S=m-1$ if $n<0)$. Finally, if n 0 apply $\Omega_{0}^{-} \frac{\mathrm{n}+\mathrm{m}-1}{2}$ times and if $\mathrm{n}<0$ apply $\Omega_{0}^{+} \frac{\mathrm{n}+\mathrm{m}-1}{2}$ times to create new double points. The resulting holonomic knot $C$ then has $W(C)=m$ and $\mathrm{S}(\mathrm{C})=\mathrm{n}$, as desired.

## 2.B Proof of Proposition 1.4

Let $f$ be a function with associated holonomic plane curve $c_{f}$ which is an immersion. If is a di eomorphism of $S^{1}$ then also $f$ gives rise to a regular
holonomic plane curve
Led $g$ bea function with regular planehol onomic curve $c_{g}$ with $W\left(c_{f}\right)=W\left(c_{g}\right)$. Perturb f and g so that they become Morse functions. Then the proof of Proposition 1.1 implies that they have the same number of local extrema. Let s, $0 \quad s \quad 1$ be a di eotopy of $S^{1}$ which moves each critical point of $f$ to a critical point of $g$ of the same index. Then the critical sets of $\hat{g}=\mathrm{g} \quad 1$ and of $f$ agree Moreover, if $t$ is local maximum (minimum) of $f$ then it is a local maximum (minimum) of $g \quad 1$. Let $(s ; r)$ be coordinates on the cylinder $S^{1} \quad \mathbb{R}$ and consider the vector eld $V(s ; r)=(f(s)-g(s)) @$. Let be the flow of $V$. If $\hat{g}$ is the function with graph $\left(\Gamma_{g}\right)$, where $\Gamma_{g}$ is the graph of $\hat{g}$, then $\hat{g}$ has a regular associated holonomic curve for each 1 and $\mathrm{g}_{\mathrm{i}}=\mathrm{f}$.

These two deformations together give the desired hol onomic regular homotopy.

## 3 Holonomic knots and front projections of Legendrian knots

## 3.A The front and complex projections of a Legendrian knot

Le $\Gamma$ bea knot in $\mathbb{R}^{3}$ with coordinates ( $x ; y ; z$ ) everywheretangent to the plane eld $\mathrm{fker}(\mathrm{dz}-\mathrm{ydx}) \mathrm{g}$. That is, $\Gamma$ is a Legendrian knot. Assume moreover that $\Gamma$ is generic among Legendrian knots, then the projection $\Gamma_{F}$ of $\Gamma$ to the $x z$-plane is a curve with transverse double points, isolated cusps, and without vertical tangencies. Moreover, given any curve in the xz-plane with these properties, thereexists a unique Legendrian knot which projects to this curve. Weassociate the following numbers to $\Gamma_{F}$ :

First we count cusps, let $\operatorname{Dcu}\left(\Gamma_{F}\right)$, $\operatorname{Ucu}\left(\Gamma_{F}\right)$, and $\operatorname{Lcu}\left(\Gamma_{F}\right)$ denote the number of down-cusps, up-cusps, and left-cusps respectively of $\Gamma_{F}$, se Figure 4.

Figure 4: (A) Down-cusp, (B) Up-cusp, and (C) left-cusp.

Second we count crossings, let $\operatorname{Ecr}\left(\Gamma_{F}\right)$ denote the number of crossing points where the tangent vectors has $x$-components of the same sign and $\operatorname{Ocr}\left(\Gamma_{F}\right)$ the number of crossing points where the tangent vectors has x-components of the opposite sign. Se Figures 5 and 6.

Figure 5: Crossing points with tangents with x-components of equal sign

Figure 6: Crossing points with tangents with $x$-components of opposite signs
The projection $\Gamma_{\mathbb{C}}$ of $\Gamma$ to the $x y$-plane is a generic knot diagram. It is straightforward to check that the invariants $\mathrm{W}\left(\Gamma_{\mathbb{C}}\right)$, where we use the orientation given by $d x$ ^ $d y$ in the $x y$-plane, and $S\left(\Gamma_{\mathbb{C}}\right)$, where we use the orientation given by $d x{ }^{\wedge} d y{ }^{\wedge} d z$ in space, can be computed from data of $\Gamma_{F}$ as follows,

$$
\begin{align*}
\mathrm{W}\left(\Gamma_{\mathbb{C}}\right) & =\frac{1}{2}\left(\operatorname{Dcu}\left(\Gamma_{F}\right)-\operatorname{Ucu}\left(\Gamma_{F}\right)\right) ;  \tag{3.1}\\
\mathrm{S}\left(\Gamma_{\mathbb{C}}\right) & =\operatorname{Ecr}\left(\Gamma_{F}\right)-\operatorname{Ocr}\left(\Gamma_{F}\right)-\operatorname{Lcu}\left(\Gamma_{F}\right): \tag{3.2}
\end{align*}
$$

## 3.B Legendrian knots associated to a holonomic one

Let C be a framed holonomic knot. We associate two Legendrian knots $\Gamma^{+}$ and $\Gamma^{-}$, everywhere tangent to $\operatorname{ker}\left(\mathrm{dx}_{1}-\mathrm{x}_{2} \mathrm{dx}_{0}\right)$, to C by describing their front projections (in the $x_{0} x_{1}$-plane). The resulting Legendrian knots lie in $\mathbb{R}^{3}$ oriented by $\mathrm{dx}_{0}{ }^{\wedge} \mathrm{dx}_{2} \wedge \mathrm{dx}_{1}>0$.
The rst step in the construction of the fronts of $\Gamma^{+}$and $\Gamma^{-}$is the same in both cases:

The points where the diagram of C has vertical tangents are all con ned to the $\mathrm{x}_{0}$-axis. Replace neighborhoods of such points in the diagram with cusped arcs as described in Figure 7. The second step however di ers:

Figure 7: Replacing vertical tangencies with cusps

To obtain the front of $\Gamma^{+}$we insert a zig-zag as in Figure 8 at all crossings in the lower half plane and kep the crossings in the upper half plane as they are

To obtain the front of $\Gamma^{-}$we insert a zig-zag as in Figure 9 at all crossings in the upper half plane and keep the crossings in the lower half plane as they are.

Figure 8: Inserting a zig-zag in the lower half plane

Figure 9: Inserting a zig-zag in the upper half plane
It is easy to check that $\Gamma^{-}\left(\Gamma^{+}\right)$is topologically isotopic to the knot $C$ in $\mathbb{R}^{3}$ equipped with the orientation $\mathrm{dx}_{0} \wedge \mathrm{dx}_{1} \wedge \mathrm{dx}_{2}>0\left(\mathrm{dx}_{0} \wedge \mathrm{dx}_{1} \wedge \mathrm{dx} 2<0\right)$.

Algebraic \& Geometric Topology, Volume 2 (2002)

## 3.C Proof of Theorem 1.2

Using $\Omega_{2}$-moves, we may obtain a closed braid representation of K . Equation (1.1) follows.

To prove (1.2), let $H_{+}(C)\left(H_{-}(C)\right)$ denote the number of intersection points of C in the upper (lower) half plane. Then $\mathrm{S}(\mathrm{C})=\mathrm{H}_{-}(\mathrm{C})-\mathrm{H}_{+}(\mathrm{C})$. As noted before $W(C)$ is the negative of the number of local minima of the function $f$ giving rise to $C$.

Le $\Gamma^{+}$and $\Gamma^{-}$be the Legendrian knots associated to $C$ as in Subsection 3.B. Then

$$
\begin{aligned}
& \operatorname{Dcu}\left(\Gamma_{F}^{+}\right)=-\mathrm{W}(\mathrm{C})+2 \mathrm{H}_{-}(\mathrm{C}) ; \\
& \operatorname{Dcu}\left(\Gamma_{F}^{-}\right)=-\mathrm{W}(\mathrm{C})+2 \mathrm{H}_{+}(\mathrm{C}) ; \\
& \operatorname{Ucu}\left(\Gamma_{F}^{+}\right)=\operatorname{Ucu}\left(\Gamma_{F}^{-}\right)=-\mathrm{W}(\mathrm{C}) ;
\end{aligned}
$$

and hence

$$
\begin{align*}
& W\left(\Gamma_{\mathbb{C}}^{+}\right)=H_{-}(\mathrm{C}) ;  \tag{3.3}\\
& \mathrm{W}\left(\Gamma_{\mathbb{C}}^{-}\right)=\mathrm{H}_{+}(\mathrm{C}): \tag{3.4}
\end{align*}
$$

Also,

$$
\begin{aligned}
& \operatorname{Lcu}\left(\Gamma_{F}^{+}\right)=-\mathrm{W}(\mathrm{C})+\mathrm{H}_{-}(\mathrm{C}) ; \\
& \operatorname{Lcu}\left(\Gamma_{F}^{-}\right)=-\mathrm{W}(\mathrm{C})+\mathrm{H}_{+}(\mathrm{C}) ; \\
& \operatorname{Ecr}\left(\Gamma_{F}^{+}\right)=\operatorname{Ocr}\left(\Gamma_{F}^{-}\right)=\mathrm{H}_{+}(\mathrm{C}) ; \\
& \operatorname{Ecr}\left(\Gamma_{F}^{-}\right)=\operatorname{Ocr}\left(\Gamma_{F}^{+}\right)=\mathrm{H}_{-}(\mathrm{C}) ;
\end{aligned}
$$

and hence

$$
\begin{align*}
& \mathrm{S}\left(\Gamma_{\mathbb{C}}^{+}\right)=\mathrm{H}_{+}(\mathrm{C})-2 \mathrm{H}_{-}(\mathrm{C})+\mathrm{W}(\mathrm{C}) ;  \tag{3.5}\\
& \mathrm{S}\left(\Gamma_{\mathbb{C}}^{-}\right)=\mathrm{H}_{-}(\mathrm{C})-2 \mathrm{H}_{+}(\mathrm{C})+\mathrm{W}(\mathrm{C}): \tag{3.6}
\end{align*}
$$

Combining (3.3) and (3.5), respectively (3.4) and (3.6) with the Bennequin inequality (1.3) yields

$$
\begin{aligned}
-S(C)+W(C) & 2 g(K)-1 \text { and } \\
S(C)+W(C) & 2 g(K)-1 ;
\end{aligned}
$$

since the genus does not depend on the orientation of the ambient space. The theorem follows.

## 4 Splitting the self linking number

Consider the diagram of a framed holonomic knot $C$. The $x_{0}$-axis divides the diagram into cyclically ordered $\operatorname{arcs}\left(X_{i} ; Y_{i}\right), i=1 ;::: ; m$, where the $X_{i}$ lies in the upper half plane, the $Y_{i}$ in the lower, and where $-m=W(C)$.
Let $\left(A_{i} ; A_{j}\right)=\left(X_{i} ; X_{j}\right)$ or $\left(A_{i} ; A_{j}\right)=\left(Y_{i} ; Y_{j}\right)$ where $i \sigma j$. De ne
$\left(A_{i} ; A_{j}\right)=\begin{array}{ll}1 & \text { if } @ A_{i} \text { is contained in an unbounded component of } \mathbb{R}-@ A_{j}, \\ 0 & \text { otherwise }\end{array}$

De ne

$$
N\left(A_{i} ; A_{j}\right)=j A_{i} \backslash A_{j} j+\left(A_{i} ; A_{j}\right) ;
$$

where $j S j$ denotes the number of points in the set $S$.
Let $X_{i}$ and $Y_{i}$ denote the preimages of $X_{i}$ and $Y_{i}$, for $i=1 ;::: ; m$. Let $x_{i}$ and $y_{i}$ denote the midpoints of $X_{i}$ and $Y_{i}$, respectively.
Consider two arcs $X_{i}$ and $X_{j}, i \in j$. Let $\gamma\left(x_{i} ; x_{j}\right)$ denote the unique oriented arc connecting $x_{i}$ to $x_{j}$ with orientation agreeing with that of thecircle. De ne the cyclic distance of $X_{i}$ and $X_{j}$ as

$$
d\left(X_{i} ; x_{j}\right)=\min ^{n} j \gamma\left(x_{i} ; x_{j}\right) \backslash f_{y_{1}} ;::: ; y_{m} g j ; j \gamma\left(x_{j} ; x_{i}\right) \backslash f y_{1} ;::: ; y_{m} g^{o}:
$$

De ne the cyclic distance of arcs $Y_{i}$ and $Y_{j}$ analogously.
De nition 4.1 De ne

$$
S_{k}(C)=\frac{1}{2} @_{f\left(Y_{i} ; Y_{j}\right): d\left(Y_{i} ; Y_{j}\right)=k g} N\left(Y_{i} ; Y_{j}\right)-\underset{f\left(X_{i} ; X_{j}\right): d\left(X_{i} ; X_{j}\right)=k g}{X} N\left(X_{i} ; X_{j}\right) A:
$$

Remark 4.2 In terms of de ning functions, the terms in the de nition of $S_{k}$ can be interpreted as follows. Let $f: S^{1}!\mathbb{R}$ be a function with associated framed holonomic knot $C$. Consider $f$ as a periodic function with period $T$ such that $f(0)=f(T)$ is the global minimum of $f$. Let $\Gamma_{f} \quad[0 ; T] \quad \mathbb{R}$ $\mathbb{R}^{2}$ denote the graph of $f$. Then the arcs $X_{i}\left(Y_{i}\right)$ are the holonomic curves corresponding to restrictions of $f$ to subintervals of $[0 ; T]$, where $f$ is increasing (decreasing). If ( $x ; y$ ) are coordinates on $\mathbb{R}^{2}$ then $j A_{i} \backslash A_{j} j$ equals the number of lines $l_{a}=f y=a g$, a $2 \mathbb{R}$ which intersect $A_{i}$ and $A_{j}$ at equal angles, and $\left(A_{i} ; A_{j}\right)=1$ if no $I_{a}$ intersect both $A_{i}$ and $A_{j}$, otherwise it is 0 .

## 4.A Proof of Theorem 1.3

We check that $S_{k}$ is invariant under framed holonomic Reidemeister moves. For $\Omega_{3}$ this is immediate.
An $\Omega_{2}^{+}$-move involving two arcs $X$ and $X{ }^{0}$ with distance $d(X ; X 9=k$ involves also two arcs $Y$ and $Y^{0}$ with $d(Y ; Y 9=k$. At the move $(X ; X 9$ and $(Y ; Y 9$ are unchanged and the change in $j X \backslash X g$ and $j Y \backslash Y g$ are the same. Hence $\mathrm{S}_{\mathrm{k}}$ remains constant.

At an $\Omega_{2}^{-}$-move involving arcs $X$ and $X^{0}, Y$ and $Y^{0}$ the change in $j X \backslash X 9$ and $j Y \backslash Y 9$ equals the change in $(X ; X 9$ and $(Y ; Y 9$, respectively. Hence $\mathrm{S}_{\mathrm{k}}$ remains constant.

To prove (1.4) note that by using the $\Omega_{2}$-moves we may move any framed holonomic knot diagram in such a way that its diagram is a closed braid with braid-axis parallel to the $x_{2}$-direction. (Thelinking number of this axis oriented in the positive $x_{2}$-direction and the holonomic knot with its natural orientation is negative) Under such deformations both $S$ and $S_{1} ;::: ; S_{n}$, remain constant. Moreover for a diagram which is a closed braid $\left(\mathrm{X}_{\mathrm{i}} ; \mathrm{X}_{\mathrm{j}}\right)=\left(\mathrm{Y}_{\mathrm{i}} ; \mathrm{Y}_{\mathrm{j}}\right)=0$ for all $\mathrm{i} ; \mathrm{j}$. Hence both the left and right hand sides of (1.4) are equal to the di erence of the number of double points in the lower and upper half planes.

## 5 Examples

The framed holonomic knots $K_{1}$ in Figure 10 and $K_{2}$ in Figure 11 both represent the unknot. Since $S\left(K_{1}\right)=S\left(K_{2}\right)=-1$ and $W\left(K_{1}\right)=W\left(K_{2}\right)=-4$, $K_{1}$ and $K_{2}$ are regularly isotopic. Since $K_{1}$ is a closed braid $\left(X_{i} ; X_{j}\right)=0=$ $\left(Y_{i} ; Y_{j}\right)$ for all $i ; j$. Noting that all three intersection points in the diagram of $K_{1}$ in the upper half plane are intersections between arcs of cyclic distance 1 , and that the two intersection points in the lower half plane are intersections of arcs of cydic distance 1 respectively 2 , we conclude that $S_{1}\left(K_{1}\right)=-2$ and $\mathrm{S}_{2}\left(\mathrm{~K}_{1}\right)=1$. A similar calculation gives $\mathrm{S}_{1}\left(\mathrm{~K}_{2}\right)=0$ and $\mathrm{S}_{2}\left(\mathrm{~K}_{2}\right)=-1$. Hence $K_{1}$ and $K_{2}$ are not framed holonomically isotopic.

The framed holonomic knots $K_{3}$ in Figure 12 and $K_{4}$ in Figure 13 both represent the connected sum of the trefoil and its mirror image. Since $\mathrm{S}\left(\mathrm{K}_{3}\right)=$ $S\left(K_{4}\right)=-1$ and $W\left(K_{3}\right)=W\left(K_{4}\right)=-4, K_{3}$ and $K_{4}$ are regularly isotopic. However, $\mathrm{S}_{1}\left(\mathrm{~K}_{3}\right)=0$ and $\mathrm{S}_{2}\left(\mathrm{~K}_{3}\right)=-1$ but $\mathrm{S}_{1}\left(\mathrm{~K}_{4}\right)=-4$ and $\mathrm{S}_{2}\left(\mathrm{~K}_{4}\right)=3$ so $K_{3}$ and $K_{4}$ are not framed holonomically isotopic.

Figure 10: The framed holonomic knot $\mathrm{K}_{1}$

Figure 11: The framed holonomic knot $\mathrm{K}_{2}$

Figure 12: The framed holonomic knot $\mathrm{K}_{3}$

Figure 13: The framed holonomic knot $\mathrm{K}_{4}$
