# The Johnson homomorphism and the second cohomology of $\mathrm{IA}_{n}$ 

Alexandra Pettet

#### Abstract

Let $F_{n}$ be the free group on $n$ generators. Define $\mathrm{IA}_{n}$ to be group of automorphisms of $F_{n}$ that act trivially on first homology. The Johnson homomorphism in this setting is a map from $\mathrm{IA}_{n}$ to its abelianization. The first goal of this paper is to determine how much this map contributes to the second rational cohomology of $\mathrm{IA}_{n}$.

A descending central series of $\mathrm{IA}_{n}$ is given by the subgroups $K_{n}^{(i)}$ which act trivially on $F_{n} / F_{n}^{(i+1)}$, the free rank $n$, degree $i$ nilpotent group. It is a conjecture of Andreadakis that $K_{n}^{(i)}$ is equal to the lower central series of $\mathrm{IA}_{n}$; indeed $K_{n}^{(2)}$ is known to be the commutator subgroup of $\mathrm{IA}_{n}$. We prove that the quotient group $K_{n}^{(3)} / \mathrm{IA}_{n}^{(3)}$ is finite for all $n$ and trivial for $n=3$. We also compute the rank of $K_{n}^{(2)} / K_{n}^{(3)}$.

## 1 Introduction

Let $\operatorname{Aut}\left(F_{n}\right)$ denote the automorphism group of the free group $F_{n}$ on generators $\left\{x_{1}, \ldots, x_{n}\right\}$. The IA-automorphism group of $F_{n}$, denoted by $\mathrm{IA}_{n}$, is defined to be the kernel of the exact sequence

$$
1 \longrightarrow \mathrm{IA}_{n} \longrightarrow \operatorname{Aut}\left(F_{n}\right) \longrightarrow \mathrm{GL}(n, \mathbb{Z}) \longrightarrow 1
$$

induced by the action of $\operatorname{Aut}\left(F_{n}\right)$ on the abelianization of $F_{n}$.
Although Nielsen studied $\mathrm{IA}_{n}$ as early as 1918, it is still the case that little is understood about this group. For instance, while there is a well-known finite set of generators, discovered by Magnus in 1934 [M], it remains unknown whether $\mathrm{IA}_{n}$ is finitely presentable for $n>3$. In 1997, Krstić-McCool proved that $\mathrm{IA}_{3}$ is not finitely presentable [KM, Theorem 1].

Magnus's set of generators for $\mathrm{IA}_{n}$ is the collection of automorphisms

$$
\left\{g_{i j}: 1 \leq i, j \leq n, i \neq j\right\} \cup\left\{f_{i j k}: 1 \leq i, j, k \leq n, j \neq i \neq k, i<j\right\}
$$

where $g_{i j}$ is defined by

$$
g_{i j}\left(x_{r}\right)= \begin{cases}x_{r} & r \neq j \\ x_{i} x_{j} x_{i}^{-1} & r=j\end{cases}
$$

and $f_{i j k}$ is defined by

$$
f_{i j k}\left(x_{r}\right)= \begin{cases}x_{r} & r \neq k \\ x_{k}\left[x_{i}, x_{j}\right] & r=k\end{cases}
$$

Recently Cohen-Pakianathan [CP], Farb [F], and Kawazumi [K] independently determined the first homology and cohomology groups of $\mathrm{IA}_{n}$ using a map based on Johnson's homomorphism for the Torelli group [J]. For a group $G$, let $G^{(1)}=G$, and let $G^{(k)}$ be $k$ th term of the lower central series. Let $H_{1}(G)$ denote the integral homology of $G$, and $H_{1}(G)^{*}$ its dual. Cohen-Pakianathan [CP, Corollary 3.5], Farb [F, Theorem 1.1], and Kawazumi [K, Theorem 6.1] proved the following:

Theorem 1.1 There exists a surjective homomorphism

$$
\tau: \mathrm{IA}_{n} \longrightarrow \wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right)^{*}
$$

Furthermore, the induced map

$$
\tau_{*}: H_{1}\left(\mathrm{IA}_{n}\right) \longrightarrow \wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right)^{*}
$$

is an isomorphism of $\mathrm{GL}(n, \mathbb{Z})$-modules. In particular, the free abelian group $H_{1}\left(\mathrm{IA}_{n}\right)$ has rank

$$
\operatorname{rank}\left(H_{1}\left(\mathrm{IA}_{n}\right)\right)=n^{2}(n-1) / 2
$$

See Section 2.3 for the definition of $\tau$. Note that the theorem implies that $\mathrm{IA}_{n}^{(2)}$ is equal to the kernel of $\tau$. Andreadakis [A] proved Theorem 1.1 for the case $n=3$.

Recall that $H_{1}\left(F_{n}\right) \simeq F_{n} / F_{n}^{(2)} \simeq \mathbb{Z}^{n}$ has a standard basis $\left\{e_{1}, \ldots, e_{n}\right\}$ with dual basis $\left\{e_{1}^{*}, \ldots, e_{n}^{*}\right\}$. The image of the Magnus generators under $\tau$ is

$$
\tau\left(g_{i j}\right)=\left(e_{i} \wedge e_{j}\right) \otimes e_{j}^{*}
$$

and

$$
\tau\left(f_{i j k}\right)=\left(e_{i} \wedge e_{j}\right) \otimes e_{k}^{*}
$$

The subgroup $\mathrm{IA}_{n}$ of $\operatorname{Aut}\left(F_{n}\right)$ is a free group analogue of the Torelli subgroup of the based mapping class group. The corresponding subgroup $\mathrm{OA}_{n}$ of the
outer automorphism group $\operatorname{Out}\left(F_{n}\right)$, gives a free group analogue of the unbased Torelli group. The group of inner automorphisms of $F_{n}$ is a normal subgroup of $\mathrm{IA}_{n}$, so there is an exact sequence

$$
1 \longrightarrow \mathrm{OA}_{n} \longrightarrow \operatorname{Out}\left(F_{n}\right) \longrightarrow \mathrm{GL}(n, \mathbb{Z}) \longrightarrow 1
$$

and a surjective homomorphism $\bar{\tau}$ from $\mathrm{OA}_{n}$ to a quotient of $\wedge^{2} H \otimes H^{*}$

$$
\bar{\tau}: \mathrm{OA}_{n} \longrightarrow\left(\wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right)^{*}\right) / H_{1}\left(F_{n}\right)
$$

Almost nothing is known about higher cohomology of $\mathrm{IA}_{n}$; it is not even known whether $H^{2}\left(\mathrm{IA}_{n}\right)$ is of finite or infinite dimension. Our main goal here is to determine the second rational cohomology of $\mathrm{IA}_{n}$ and $\mathrm{OA}_{n}$ coming from the homomorphisms $\tau$. In papers by Hain [H] and Sakasai [Sak], the Johnson homomorphism is used to understand the second and third rational cohomology groups of the Torelli group. In this paper, we use their method to compute the kernel of the homomophism

$$
\tau^{*}: H^{2}\left(\bigwedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right)^{*}, \mathbb{Q}\right) \longrightarrow H^{2}\left(\mathrm{IA}_{n}, \mathbb{Q}\right)
$$

and an analogue for $\mathrm{OA}_{n}$.

Theorem 1.2 The kernel of the homomorphism

$$
\tau^{*}: H^{2}\left(\wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right)^{*}, \mathbb{Q}\right) \longrightarrow H^{2}\left(\mathrm{IA}_{n}, \mathbb{Q}\right)
$$

decomposes into simple $\mathrm{GL}(n, \mathbb{Q})$-modules as

$$
\operatorname{ker}\left(\tau^{*}\right) \simeq \Phi_{0, \ldots, 0,1,0,-1} \oplus \Phi_{1,0, \ldots, 0,1,1,-2} .
$$

The kernel of the homomorphism

$$
\bar{\tau}^{*}: H^{2}\left(\left(\wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right)^{*}\right) / H_{1}\left(F_{n}\right), \mathbb{Q}\right) \longrightarrow H^{2}\left(\mathrm{OA}_{n}, \mathbb{Q}\right)
$$

is the simple module

$$
\operatorname{ker}\left(\bar{\tau}^{*}\right) \simeq \Phi_{1,0, \ldots, 0,1,1,-2} .
$$

The notation requires some explanation. Briefly, each $\Phi_{\alpha}$ represents an isomorphism class of a simple $\mathrm{GL}(n, \mathbb{Q})$-module; the class is uniquely determined by the subscript $\alpha$. This notation is described in more detail in Section 2.1 below and is explained comprehensively in Fulton-Harris [FH].
A key input is a "higher" Johnson homomorphism $\tau^{(2)}$, defined on $\operatorname{ker}(\tau)$ :
Theorem 1.3 There exists a homomorphism

$$
\tau^{(2)}: \mathrm{IA}_{n}^{(2)} \longrightarrow\left(\wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right) / \wedge^{3} H_{1}\left(F_{n}\right)\right) \otimes H_{1}\left(F_{n}\right)^{*}
$$

and a homomorphism

$$
\bar{\tau}^{(2)}: \mathrm{OA}_{n}^{(2)} \longrightarrow\left(\left(\bigwedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right) / \wedge^{3} H_{1}\left(F_{n}\right)\right) \otimes H_{1}\left(F_{n}\right)^{*}\right) / \wedge^{2} H_{1}\left(F_{n}\right)
$$

The kernel of $\tau^{(2)}$ (respectively, $\left.\bar{\tau}^{(2)}\right)$ contains $\mathrm{IA}_{n}^{(3)}$ (respectively, $\mathrm{OA}_{n}^{(3)}$ ) as a subgroup of finite index. Tensoring each target space with $\mathbb{Q}$, the image of $\mathrm{IA}_{n}$ in

$$
\left(\bigwedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right) / \wedge^{3} H_{1}\left(F_{n}\right)\right) \otimes H_{1}\left(F_{n}\right)^{*} \otimes \mathbb{Q}
$$

is isomorphic as a $\mathrm{GL}(n, \mathbb{Q})$-representation to

$$
\Phi_{0,1,0, \ldots, 0} \oplus \Phi_{1,1,0, \ldots, 0,1,-1}
$$

and the image of $\mathrm{OA}_{n}$ in

$$
\left(\left(\wedge^{2} H_{1}\left(F_{n}\right) \otimes H_{1}\left(F_{n}\right) / \wedge^{3} H_{1}\left(F_{n}\right)\right) \otimes H_{1}\left(F_{n}\right)^{*} / \wedge^{2} H_{1}\left(F_{n}\right)\right) \otimes \mathbb{Q}
$$

is isomorphic to $\Phi_{1,1,0, \ldots, 0,1,-1}$.
Theorem 1.3 is an analogue of a result of Morita's for the Torelli group [Mo]. Satoh has determined the image of $\tau^{(2)}$ over $\mathbb{Z}$ in recent work [Sat].
An interesting filtration $K_{n}^{(i)}$ of $\mathrm{IA}_{n}$ is given by the subgroups

$$
K_{n}^{(i)}=\operatorname{ker}\left(\operatorname{Aut}\left(F_{n}\right) \longrightarrow \operatorname{Aut}\left(F_{n} / F_{n}^{(i)}\right)\right)
$$

Following from the definitions and Theorem 1.1, we have $K_{n}^{(1)}=\mathrm{IA}_{n}$ and $K_{n}^{(2)}=\left[\mathrm{IA}_{n}, \mathrm{IA}_{n}\right]$. Andreadakis proved that $K_{n}^{(i)}$ is equal to the lower central series in the case $n=2$ [A, Theorem 6.1], and that the first three terms of these series coincide in the case $n=3$ [A, Theorem 6.2]. This led him to conjecture that these two series might be equal for all $n$. We reprove his result for $n=3$ and show that the quotient $K_{n}^{(3)} / \mathrm{IA}_{n}^{(3)}$ is finite for all $n$.

Corollary 1.4 The quotient $K_{n}^{(3)} / \mathrm{IA}_{n}^{(3)}$ is finite for all $n$ and trivial for $n=3$. The rank of the free abelian group $K_{n}^{(2)} / K_{n}^{(3)}$ is

$$
\operatorname{rank}\left(K_{n}^{(2)} / K_{n}^{(3)}\right)=\frac{1}{3} n^{2}\left(n^{2}-4\right)+\frac{1}{2} n(n-1) .
$$

Andreadakis computed the rank of $K_{n}^{(2)} / K_{n}^{(3)}$ only for the case $n=3$, where he determined the rank to be 18 [A, Theorem 6.2].
The author would like to thank her advisor Professor Benson Farb for his enthusiasm, encouragement, and direction. She is also grateful to Fred Cohen, Daniel Biss, David Ogilvie, and Ben Wieland for their helpful explanations and suggestions, and to Professor Richard Hain for explaining how to detect elements in the kernel of $\tau^{*}$. The author was partially supported by an NSERC PGSA fellowship.

## 2 Preliminaries

### 2.1 Notation

The reader is referred to Fulton-Harris [FH] for the representation theory in this paper. Of particular relevance are Sections 1,15 and 24.
Any finite dimensional representation of $\mathrm{GL}(n, \mathbb{C})$ decomposes as a tensor product of a representation of $\operatorname{SL}(n, \mathbb{C})$ with a one-dimensional representation. Let $\mathfrak{g l}(n, \mathbb{C})$ (respectively, $\mathfrak{s l}(n, \mathbb{C})$ ) be the Lie algebra of $\mathrm{GL}(n, \mathbb{C})$ (respectively, $\operatorname{SL}(n, \mathbb{C}))$. The finite-dimensional representations of $\mathrm{SL}(n, \mathbb{C})$ and $\mathfrak{s l}(n, \mathbb{C})$ are in natural bijection. Let $L_{i}$ be the element in the dual of the Cartan subalgebra of diagonal matrices in $\mathfrak{s l}(n, \mathbb{C})$ which sends a matrix to its $i$ th diagonal entry. Any irreducible representation of $\mathrm{GL}(n, \mathbb{C})$ is determined up to isomorphism by a unique highest weight for $\operatorname{SL}(n, \mathbb{C})$ and a power of the determinant. This information corresponds to a sum

$$
a_{1} L_{1}+a_{2}\left(L_{1}+L_{2}\right)+\cdots+a_{n}\left(L_{1}+L_{2}+\cdots+L_{n}\right)
$$

where $a_{i}$ is a non-negative integer, $1 \leq i \leq n-1$, and $a_{n} \in \mathbb{Z}$. We let $\Phi_{a_{1}, a_{2}, \ldots, a_{n}}$ denote the representation corresponding to this sum. For example, the standard representation of $\operatorname{GL}(n, \mathbb{C})$ is given by $\Phi_{1,0, \ldots, 0}$, and its dual is given by $\Phi_{0, \ldots, 0,1,-1}$.
All of these representations are defined over $\mathbb{Q}$, so they can be considered as irreducible representations of $\operatorname{GL}(n, \mathbb{Q})$ and $\mathfrak{g l}(n, \mathbb{Q})$.

### 2.2 Deriving an exact sequence

The following exact sequence will be used in the computations underlying Theorem 1.2. While this sequence is implicit in Sullivan's paper [Su], we include its derivation here for completeness.

Lemma 2.1 For any group $G$ with finite $\operatorname{rank} H^{1}(G, \mathbb{Q})$, the following sequence is exact:

$$
0 \longrightarrow \operatorname{Hom}\left(G^{(2)} / G^{(3)}, \mathbb{Q}\right) \longrightarrow \wedge^{2} H^{1}(G, \mathbb{Q}) \longrightarrow H^{2}(G, \mathbb{Q})
$$

The left hand map is induced by the surjective map

$$
\begin{aligned}
& \wedge^{2} G_{a b} \longrightarrow G^{(2)} / G^{(3)} \\
& g_{1} \wedge g_{2} \mapsto\left[g_{1}, g_{2}\right] G^{(3)}
\end{aligned}
$$

and the isomorphism

$$
\wedge^{2} H^{1}(G, \mathbb{Q}) \simeq \operatorname{Hom}\left(\bigwedge^{2} G_{a b}, \mathbb{Q}\right)
$$

The right hand map of the sequence comes from the cup product on cohomology.
Given an exact sequence of groups

$$
1 \longrightarrow G^{(2)} \longrightarrow G \longrightarrow G_{a b} \longrightarrow 0
$$

the Hochschild-Serre spectral sequence yields the five-term exact sequence

$$
\begin{aligned}
0 \longrightarrow H^{1}\left(G_{a b}, H^{0}\left(G^{(2)}, \mathbb{Q}\right)\right) \longrightarrow H^{1}(G, \mathbb{Q}) & \longrightarrow H^{0}\left(G_{a b}, H^{1}\left(G^{(2)}, \mathbb{Q}\right)\right) \longrightarrow \\
& \longrightarrow H^{2}\left(G_{a b}, H^{0}\left(G^{(2)}, \mathbb{Q}\right)\right) \longrightarrow H^{2}(G, \mathbb{Q}) .
\end{aligned}
$$

(For details, consult Section 7.6 of Brown's book [B], particularly Corollary 6.4.) Now $H^{1}\left(G_{a b}, \mathbb{Q}\right)$ and $H^{1}(G, \mathbb{Q})$ are isomorphic and finite rank, so the sequence immediately reduces to

$$
0 \longrightarrow H^{0}\left(G_{a b}, H^{1}\left(G^{(2)}, \mathbb{Q}\right)\right) \longrightarrow H^{2}\left(G_{a b}, \mathbb{Q}\right) \longrightarrow H^{2}(G, \mathbb{Q}) .
$$

We also have $H^{2}\left(G_{a b}, \mathbb{Q}\right)=\wedge^{2} H^{1}(G, \mathbb{Q})$, so we are done once we interpret $H^{0}\left(G_{a b}, H^{1}\left(G^{(2)}, \mathbb{Q}\right)\right)$. By definition, it is the set of invariants of $\left.H^{1}\left(G^{(2)}, \mathbb{Q}\right)\right)=$ $\operatorname{Hom}\left(G^{(2)}, \mathbb{Q}\right)$ under the action of $G_{a b}$. This action is given by lifting $G_{a b}$ to $G$ and acting by conjugation. Thus $H^{0}\left(G_{a b}, H^{1}\left(G^{(2)}, \mathbb{Q}\right)\right)$ is the set of homomorphisms of $\operatorname{Hom}\left(G^{(2)}, \mathbb{Q}\right)$ which are trivial on $G^{(3)}$, i.e.

$$
H^{0}\left(G_{a b}, H^{1}\left(G^{(2)}, \mathbb{Q}\right)\right)=\operatorname{Hom}\left(G^{(2)} / G^{(3)}, \mathbb{Q}\right)
$$

### 2.3 A higher Johnson homomorphism

Unless otherwise stated, $n \geq 3$ will be fixed, IA will denote $\mathrm{IA}_{n}$, and $F$ will denote $F_{n}$.

In this subsection, we define a map

$$
\tau^{(2)}: \mathrm{IA}^{(2)} \longrightarrow\left(\wedge^{2} H_{1}(F) \otimes H_{1}(F) / \wedge^{3} H_{1}(F)\right) \otimes H_{1}(F)^{*}
$$

which is analogous to the Johnson homomorphism for IA. A generalization of this map to all $\mathrm{IA}^{(n)}$ and to some related classes of groups is discussed in [CP], $[\mathrm{K}]$, and [Sat].
We begin with a map

$$
\delta^{(2)}: \mathrm{IA}^{(2)} \longrightarrow \operatorname{Hom}\left(H_{1}(F), F^{(3)} / F^{(4)}\right)
$$

defined as follows:

For $f \in \mathrm{IA}^{(2)}$, map $f$ to $\left(x \mapsto f(\tilde{x}) \tilde{x}^{-1}\right)$ where $\tilde{x}$ is a lift of $x \in F / F^{(2)}$ to $F / F^{(4)}$. From the fact that $\mathrm{IA}^{(2)}$ acts as the identity on both $F / F^{(2)}$ and $F^{(2)} / F^{(4)}$, it is straightfoward to verify that $\delta^{(2)}(f)$ is a well-defined homomorphism from $H_{1}(F)$ to $F^{(2)} / F^{(4)}$. Furthermore, since $F / F^{(4)}$ factors through $F / F^{(3)}$, and since $\mathrm{IA}^{(2)}$ also acts as the identity on $F / F^{(3)}$, it follows that $f(\tilde{x}) \tilde{x}^{-1}$ actually lies in $F^{(3)} / F^{(4)}$. Therefore we have $\delta^{(2)}(f) \in$ $\operatorname{Hom}\left(H_{1}(F), F^{(3)} / F^{(4)}\right)$.
The GL $(n, \mathbb{Z})$-module $\operatorname{Hom}\left(H_{1}(F), F^{(3)} / F^{(4)}\right)$ is isomorphic to

$$
\left(\wedge^{2} H_{1}(F) \otimes H_{1}(F) / \wedge^{3} H_{1}(F)\right) \otimes H_{1}(F)^{*} .
$$

We define the map $\tau^{(2)}$ to be the composition of $\delta^{(2)}$ with this isomorphism.
Since $\mathrm{IA}^{(3)}$ acts as the identity on $F / F^{(4)}$, it lies in the kernel of $\tau^{(2)}$.

## 3 The kernel of the Johnson homomorphism on second cohomology

There are three main steps to the proof of Theorem 1.2, and we will first restrict our attention to IA, postponing OA until subsection 3.4. First we decompose $\left(H_{1}(F) \wedge H_{1}(F)\right) \otimes H_{1}(F)^{*}$ into simple $\mathrm{GL}(n, \mathbb{Q})$-submodules. The kernel of $\tau$ is a $\mathrm{GL}(n, \mathbb{Q})$-submodule, so is a direct sum of a subset of these simple submodules. Next we use the exact sequence of Section 2.2 to identify isomorphism classes of simple modules contained in the kernel of $\tau^{*}$. Finally, we use the method of Hain $[\mathrm{H}]$ and Sakasai $[\mathrm{Sak}]$ to find classes which are not in the kernel. Steps 2 and 3 exhaust the set of classes in the decomposition of $\left(H_{1}(F) \wedge H_{1}(F)\right) \otimes H_{1}(F)^{*}$, showing that the terms identified in the step 2 are the only ones in the kernel.

Once the computations underlying Theorem 1.2 are complete, Theorem 1.3 and Corollary 1.4 are straightforward. The fourth subsection below contains their proofs.

### 3.1 Module decompositions

We begin with a decomposition of the relevant $\mathrm{GL}(n, \mathbb{Q})$-modules into direct sums of simple submodules. Let $H=H_{1}(F)$ and

$$
U=\wedge^{2} H \otimes H^{*}
$$

Let $H_{\mathbb{Q}}$ and $U_{\mathbb{Q}}$ denote the tensor product with $\mathbb{Q}$ of the spaces $H$ and $U$, respectively. The action of $\operatorname{GL}(n, \mathbb{Q})$ on $H_{\mathbb{Q}}^{*}$ will be dual to that on $H_{\mathbb{Q}}$.

Direct computation yields the following two lemmas.
Lemma 3.1 $U_{\mathbb{Q}}^{*}$ decomposes into a direct sum of simple $\mathrm{GL}(n, \mathbb{Q})$-submodules as:

$$
U_{\mathbb{Q}}^{*} \simeq \begin{cases}\Phi_{2,0,-1} \oplus \Phi_{0,1,-1} & n=3 \\ \Phi_{1,0, \ldots, 0,1,0,-1} \oplus \Phi_{0, \ldots, 0,1,-1} & n \geq 3\end{cases}
$$

Lemma 3.2 As a $\mathrm{GL}(n, \mathbb{Q})$-module, $\wedge^{2} U_{\mathbb{Q}}^{*}$ decomposes as:

$$
\wedge^{2} U_{\mathbb{Q}}^{*} \simeq \begin{cases}2 \Phi_{1,0,-1} \oplus 2 \Phi_{2,1,-2} & n=3 \\ \Phi_{2,0,0,-1} \oplus 3 \Phi_{0,1,0,-1} \oplus \Phi_{0,3,0,-2} \oplus \Phi_{3,0,1,-2} \oplus 2 \Phi_{1,1,1,-2} & n=4 \\ 2 \Phi_{1,1,0,0,-1} \oplus 3 \Phi_{0,0,1,0,-1} \oplus \Phi_{0,1,2,0,-2} \oplus & \\ \oplus \Phi_{2,1,0,1,-2} \oplus 2 \Phi_{1,0,1,1,-2} & n=5\end{cases}
$$

For $n=6$ :

$$
\begin{aligned}
\wedge^{2} U_{\mathbb{Q}}^{*} \simeq \Phi_{0,2,0,0,0,-1} \oplus 2 \Phi_{1,0,1,0,0,-1} & \oplus 3 \Phi_{0,0,0,1,0,-1} \oplus \\
& \oplus \Phi_{0,1,0,2,0,-2} \oplus \Phi_{2,0,1,0,1,-2} \oplus 2 \Phi_{1,0,0,1,1,-2}
\end{aligned}
$$

For $n \geq 7$ :

$$
\begin{aligned}
\wedge^{2} U_{\mathbb{Q}}^{*} \simeq \Phi_{0,1,0, \ldots, 0,1,0,0,0,-1} \oplus & 2 \Phi_{1,0, \ldots, 0,1,0,0,-1} \oplus 3 \Phi_{0, \ldots, 0,1,0,-1} \oplus \\
& \oplus \Phi_{0,1,0, \ldots, 0,2,0,-2} \oplus \Phi_{2,0, \ldots, 0,1,0,1,-2} \oplus 2 \Phi_{1,0, \ldots, 0,1,1,-2}
\end{aligned}
$$

### 3.2 A lower bound on $\operatorname{ker}\left(\tau^{*}\right)$

The key to finding terms in the kernel of $\tau^{*}$ comes from the following diagram:

The bottom line is the sequence of Lemma 2.1. The right hand horizontal maps are the cup product on cohomology; the top one is an isomorphism since $U$ is abelian. The diagram commutes by naturality of the cup product. The vertical maps are induced by $\tau$ on second cohomology. The left vertical map is an isomorphism by Theorem 1.1, so there exists an injective homomorphism from
$\operatorname{Hom}\left(\mathrm{IA}^{(2)} / \mathrm{IA}^{(3)}, \mathbb{Q}\right)$ to $\wedge^{2} H^{1}(U, \mathbb{Q})$. Every map is equivariant with respect to the action of $\operatorname{Aut}(F)$. We can deduce from the diagram that the kernel of

$$
\tau^{*}: H^{2}(U, \mathbb{Q}) \longrightarrow H^{2}(\mathrm{IA}, \mathbb{Q})
$$

is precisely

$$
\operatorname{ker}\left(\tau^{*}\right)=\operatorname{image}\left(\operatorname{Hom}\left(\mathrm{IA}^{(2)} / \mathrm{IA}^{(3)}, \mathbb{Q}\right)\right) \subset \wedge^{2} H^{1}(U, \mathbb{Q})
$$

a $\operatorname{GL}(n, \mathbb{Q})$-submodule of $\wedge^{2} H^{1}(U, \mathbb{Q})$.
A first approximation of this image is achieved by considering the map $\tau^{(2)}$ defined in Section 2.3. The target space $\operatorname{Hom}\left(H, F^{(2)} / F^{(3)}\right) \otimes \mathbb{Q}$ is isomorphic as a $\operatorname{GL}(n, \mathbb{Q})$-module to

$$
\left(\wedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}} / \wedge^{3} H_{\mathbb{Q}}\right) \otimes H_{\mathbb{Q}}^{*}
$$

which decomposes as

$$
\Phi_{0,1,0, \ldots, 0} \oplus \Phi_{1,1,0, \ldots, 0,1,-1} \oplus \Phi_{2,0, \ldots, 0} .
$$

Consider the element $\left[g_{12}, g_{21}\right]$ in $\mathrm{IA}^{(2)}$. This acts on the generators of $F$ by

$$
x_{r} \mapsto \begin{cases}{\left[\left[x_{1}, x_{2}\right], x_{r}\right] x_{r}} & r \in\{1,2\} \\ x_{r} & r \notin\{1,2\} .\end{cases}
$$

Thus [ $g_{12}, g_{21}$ ] maps by $\tau^{(2)}$ to (the equivalence class of)

$$
\left(e_{1} \wedge e_{2}\right) \otimes e_{1} \otimes e_{1}^{*}+\left(e_{1} \wedge e_{2}\right) \otimes e_{2} \otimes e_{2}^{*}
$$

in $\left(\bigwedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}} / \bigwedge^{3} H_{\mathbb{Q}}\right) \otimes H_{\mathbb{Q}}^{*}$.
Now consider the $\mathrm{GL}(n, \mathbb{Q})$-equivariant map

$$
\left(\wedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}} / \wedge^{3} H_{\mathbb{Q}}\right) \otimes H_{\mathbb{Q}}^{*} \longrightarrow H_{\mathbb{Q}}^{\otimes 3} \otimes H_{\mathbb{Q}}^{*}
$$

defined by

$$
\begin{aligned}
& (a \wedge b) \otimes c \otimes d^{*} \mapsto \\
& \quad a \otimes b \otimes c \otimes d^{*}-b \otimes a \otimes c \otimes d^{*}+c \otimes b \otimes a \otimes d^{*}-b \otimes c \otimes a \otimes d^{*}
\end{aligned}
$$

and the $\mathrm{GL}(n, \mathbb{Q})$-equivariant map

$$
H_{\mathbb{Q}}^{\otimes 3} \otimes H_{\mathbb{Q}}^{*} \longrightarrow \wedge^{2} H_{\mathbb{Q}}
$$

defined by

$$
a \otimes b \otimes c \otimes d^{*} \mapsto d^{*}(c) a \wedge b .
$$

Applying the composition of these maps to

$$
\left(e_{1} \wedge e_{2}\right) \otimes e_{1} \otimes e_{1}^{*}+\left(e_{1} \wedge e_{2}\right) \otimes e_{2} \otimes e_{2}^{*}
$$

gives

$$
6\left(e_{1} \wedge e_{2}\right)
$$

which is a highest weight vector for the module $\Phi_{0,1,0, \ldots, 0,0}$.
Let $E_{i j}$ be the matrix in $\mathfrak{g l}(n, \mathbb{Q})$ with a 1 in the $i j$ th place and 0 's everywhere else. Applying to the vector

$$
\left(e_{1} \wedge e_{2}\right) \otimes e_{1} \otimes e_{1}^{*}+\left(e_{1} \wedge e_{2}\right) \otimes e_{2} \otimes e_{2}^{*}
$$

the map

$$
\begin{aligned}
& (a \wedge b) \otimes c \otimes d^{*} \mapsto \\
& \quad a \otimes b \otimes c \otimes d^{*}-b \otimes a \otimes c \otimes d^{*}+c \otimes b \otimes a \otimes d^{*}-b \otimes c \otimes a \otimes d^{*}
\end{aligned}
$$

followed by $E_{1 n}$, and then by

$$
a \otimes b \otimes c \otimes d^{*} \mapsto(a \wedge b) \otimes c \otimes d^{*}
$$

we obtain

$$
-4\left(e_{1} \wedge e_{2}\right) \otimes e_{1} \otimes e_{n}^{*}
$$

This is a highest weight vector for the irreducible representation corresponding to $\Phi_{1,1,0, \ldots, 0,1,-1}$.

A simple $\mathrm{GL}(n, \mathbb{Q})$-module is equal to the orbit of its highest weight by the action of $\operatorname{GL}(n, \mathbb{Q})$. Since we have found highest weights for $\Phi_{0,1,0, \ldots, 0,0}$ and $\Phi_{1,1,0, \ldots, 0,1,-1}$ in the image of the $\operatorname{GL}(n, \mathbb{Q})$-invariant map $\tau^{(2)}$, both modules are contained in the image of $\tau^{(2)}$. Therefore the dual module

$$
\Phi_{0, \ldots, 0,1,0,-1} \oplus \Phi_{1,0, \ldots, 0,1,1,-2}
$$

is contained in the kernel of $\tau^{*}$.

### 3.3 An upper bound on $\operatorname{ker}\left(\tau^{*}\right)$

In this subsection, we make use of the fact that elements in the image of $\tau_{*}: H_{2}(\mathrm{IA}, \mathbb{Q}) \longrightarrow H_{2}(U, \mathbb{Q})$ correspond to elements in the dual $H^{2}(\mathrm{IA}, \mathbb{Q})$ which lie outside of the kernel of $\tau^{*}$. This will give us an upper bound on $\operatorname{ker}\left(\tau^{*}\right)$.

If two elements $g_{1}$ and $g_{2}$ of a group $G$ commute, there is a homomorphism

$$
\zeta: \mathbb{Z}^{2} \longrightarrow G
$$

defined by mapping the two standard generators of $\mathbb{Z}^{2}$ to $g_{1}$ and $g_{2}$, inducing a map

$$
\mathbb{Z} \simeq H_{2}\left(\mathbb{Z}^{2}\right) \longrightarrow H_{2}(G)
$$

The image of the generator $1 \in H_{2}\left(\mathbb{Z}^{2}\right)$ in $H_{2}(G)$ is known as an abelian cycle, for which we write

$$
\left\{g_{1}, g_{2}\right\}:=\operatorname{image}\left(\zeta_{*}(1)\right) \in H_{2}(G) .
$$

In general, this element may be zero. In our case, we identify some abelian cycles in $H_{2}(\mathrm{IA}, \mathbb{Q})$ and compute their image in $H_{2}(U, \mathbb{Q})$. These turn out to be nonzero, giving us nonzero cycles in the image of $\tau_{*}$ in $H_{2}(\mathrm{IA}, \mathbb{Q})$. We list below a set of $\mathrm{GL}(n, \mathbb{Q})$-equivariant homomorphisms which, pre-composed with $\tau$, will detect these cycles.

First define $\mathrm{GL}(n, \mathbb{Q})$-homomorphisms:

- $f_{1}: \wedge^{2}\left(\wedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}}^{*}\right) \longrightarrow\left(\bigwedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}}^{*}\right)^{\otimes 2}$

$$
\left(a_{1} \wedge b_{1} \otimes c_{1}^{*}\right) \wedge\left(a_{2} \wedge b_{2} \otimes c_{2}^{*}\right) \mapsto
$$

$$
\left(\left(a_{1} \wedge b_{1} \otimes c_{1}^{*}\right) \otimes\left(a_{2} \wedge b_{2} \otimes c_{2}^{*}\right)\right)-\left(\left(a_{2} \wedge b_{2} \otimes c_{2}^{*}\right) \otimes\left(a_{1} \wedge b_{1} \otimes c_{1}^{*}\right)\right)
$$

- $f_{2}:\left(\wedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}}^{*}\right)^{\otimes 2} \longrightarrow\left(H_{\mathbb{Q}}^{\otimes 2} \otimes H_{\mathbb{Q}}^{*}\right)^{\otimes 2}$

$$
\left(a_{1} \wedge b_{1} \otimes c_{1}^{*}\right) \otimes\left(a_{2} \wedge b_{2} \otimes c_{2}^{*}\right) \mapsto
$$

$$
\left.\left(\left(a_{1} \otimes b_{1}-b_{1} \otimes a_{1}\right) \otimes c_{1}^{*}\right) \otimes\left(\left(a_{2} \otimes b_{2}-b_{2} \otimes a_{2}\right) \otimes c_{2}^{*}\right)\right)
$$

and let $f$ be the composition:

$$
f=f_{2} \circ f_{1}: \wedge^{2} U_{\mathbb{Q}} \longrightarrow\left(H_{\mathbb{Q}}^{\otimes 2} \otimes H_{\mathbb{Q}}^{*}\right)^{\otimes 2}
$$

Define a vector $v \in\left(H_{\mathbb{Q}}^{\otimes 2} \otimes H_{\mathbb{Q}}^{*}\right)^{\otimes 2}$ by

$$
v=\left(a_{1} \otimes b_{1} \otimes c_{1}^{*}\right) \otimes\left(a_{2} \otimes b_{2} \otimes c_{2}^{*}\right) .
$$

The following set of $\mathrm{GL}(n, \mathbb{Q})$-homomorphisms are defined on the image of $f$ :

- $g_{1}(v)=c_{1}^{*}\left(b_{2}\right) c_{2}^{*}\left(b_{1}\right)\left(a_{1} \wedge a_{2}\right) \in \wedge^{2} H_{\mathbb{Q}}$
- $g_{2}(v)=c_{1}^{*}\left(b_{1}\right) c_{2}^{*}\left(b_{2}\right)\left(a_{1} \wedge a_{2}\right) \in \wedge^{2} H_{\mathbb{Q}}$
- $h_{1}(v)=c_{1}^{*}\left(b_{1}\right)\left(a_{1} \otimes a_{2} \otimes b_{2} \otimes c_{2}^{*}\right) \in H_{\mathbb{Q}}^{\otimes 3} \otimes H_{\mathbb{Q}}^{*}$
- $h_{2}(v)=c_{1}^{*}\left(b_{2}\right)\left(a_{1} \otimes a_{2} \otimes b_{1} \otimes c_{2}^{*}\right) \in H_{\mathbb{Q}}^{\otimes 3} \otimes H_{\mathbb{Q}}^{*}$
- $k(v)=\left(a_{1} \wedge b_{1}\right) \otimes\left(a_{2} \wedge b_{2}\right) \otimes\left(c_{1}^{*} \wedge c_{2}^{*}\right) \in\left(\wedge^{2} H_{\mathbb{Q}}\right)^{\otimes 2} \otimes \wedge^{2} H_{\mathbb{Q}}^{*}$
- $l(v)=\left(a_{1} \wedge a_{2} \wedge b_{1}\right) \otimes b_{2} \otimes c_{1}^{*} \otimes c_{2}^{*} \in \wedge^{3} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}} \otimes\left(H_{\mathbb{Q}}^{*}\right)^{\otimes 2}$
- $m(v)=c_{1}^{*}\left(b_{1}\right)\left(a_{1} \otimes\left(a_{2} \wedge b_{2}\right) \otimes c_{2}^{*}\right) \in H_{\mathbb{Q}} \otimes \wedge^{2} H_{\mathbb{Q}} \otimes H_{\mathbb{Q}}^{*}$
- $n(v)=\left(a_{1} \wedge a_{2} \wedge b_{1} \wedge b_{2}\right) \otimes\left(c_{1}^{*} \wedge c_{2}^{*}\right) \in \wedge^{4} H_{\mathbb{Q}} \otimes \wedge^{2} H_{\mathbb{Q}}^{*}$

This completes the list of required homomorphisms. We work through proving that there are two terms in the isomorphism class of $\Phi_{0, \ldots, 0,1,0,-1}$ in some detail. For the remaining terms, only the abelian cycles and the homomorphisms needed to perform the computations are given.
Consider the abelian cycles

$$
\begin{aligned}
& \omega_{1}=\left\{g_{12} g_{1 n}, g_{2 n}\right\} \\
& \omega_{2}=\left\{g_{13}, g_{2 n}\right\} \\
& \omega_{3}=\left\{f_{12 n}, g_{3(n-1)}\right\}
\end{aligned}
$$

of $H_{2}(\mathrm{IA}, \mathbb{Q})$. For $\omega_{2}$ and $\omega_{3}$, we must have $n>3$. By direct computation, we have

$$
\tau_{*}\left(\omega_{1}\right)=\left(e_{1} \wedge e_{2} \otimes e_{2}^{*}+e_{1} \wedge e_{n} \otimes e_{n}^{*}\right) \wedge\left(e_{2} \wedge e_{n} \otimes e_{n}^{*}\right)
$$

Applying $g_{1} \circ f$, we obtain $2\left(e_{1} \wedge e_{2}\right)$, a highest weight for the representation $\Phi_{0,1,0, \ldots, 0,0}$, implying that the dual representation $\Phi_{0, \ldots, 0,1,0,-1}$ is not in the kernel of $\tau^{*}$.

Now compute:

$$
\tau_{*}\left(\omega_{2}\right)=\left(e_{1} \wedge e_{3} \otimes e_{3}^{*}\right) \wedge\left(e_{2} \wedge e_{n} \otimes e_{n}^{*}\right)
$$

Notice that this vector is in the kernel of $g_{1} \circ f$. Applying $g_{2} \circ f$ to $\tau_{*}\left(\omega_{2}\right)$, we again obtain $2\left(e_{1} \wedge e_{2}\right)$, giving us a second submodule of $H^{2}(U, \mathbb{Q})$ in the class $\Phi_{0, \ldots, 0,1,0,-1} \operatorname{not} \operatorname{in} \operatorname{ker}\left(\tau^{*}\right)$.
The simple module $\Phi_{1,0, \ldots, 0,1,0,0,-1}$ appears with multiplicity two in $H^{2}(U, \mathbb{Q})$, so we can use

$$
h_{2} \circ f \circ E_{3 n} \circ \tau_{*}\left(\omega_{1}\right)
$$

and

$$
h_{1} \circ f \circ \tau_{*}\left(\omega_{3}\right)
$$

to show that both of these terms are in the image of $\tau_{*}$.
We list here four more $\operatorname{GL}(n, \mathbb{Q})$-homomorphisms and abelian cycles which give highest weights of submodules whose dual modules are not in $\operatorname{ker}\left(\tau^{*}\right)$ :

- $k \circ f \circ E_{2(n-1)} \circ E_{1 n} \circ \tau_{*}\left(\omega_{1}\right)$ is a highest weight for the submodule of $H_{2}(U, \mathbb{Q})$ whose dual is $\Phi_{0,1,0, \ldots, 0,2,0,-2}$ in $H^{2}(U, \mathbb{Q})$.
- $l \circ f \circ E_{3 n} \circ E_{1 n} \circ \tau_{*}\left(\omega_{2}\right)$ is a highest weight for the module whose dual is $\Phi_{2,0, \ldots, 0,1,0,1,-2}$.
- $m \circ f \circ E_{14} \circ E_{4 n} \circ \tau_{*}\left(\omega_{1}\right)$ is a highest weight for the module whose dual is $\Phi_{1,0, \ldots, 0,1,1,-2}$.
- $n \circ f \circ E_{3(n-1)} \circ E_{4 n} \circ \tau_{*}\left(\omega_{2}\right)$ is a highest weight for the module whose dual is $\Phi_{0,1,0, \ldots, 0,1,0,0,0,-1}$.

The Johnson homomorphism and the second cohomology of $\mathrm{IA}_{n}$

### 3.4 Conclusion of the proofs

The computations needed to prove the theorems for IA are complete. Those of the previous subsection show that the submodule

$$
\begin{aligned}
2 \Phi_{0, \ldots, 0,1,0,-1} & \oplus 2 \Phi_{1,0, \ldots, 0,1,0,0,-1} \oplus \Phi_{0,1,0, \ldots, 0,2,0,-2} \oplus \\
& \oplus \Phi_{2,0, \ldots, 0,1,0,1,-2} \oplus \Phi_{1,0, \ldots, 0,1,1,-2} \oplus \Phi_{0,1,0, \ldots, 0,1,0,0,0,-1}
\end{aligned}
$$

of $H^{2}(U, \mathbb{Q})$ is not in the kernel of $\tau^{*}$. Recall that in subsection 3.2, we proved that the submodule

$$
\Phi_{0, \ldots, 0,1,0,-1} \oplus \Phi_{1,0, \ldots, 0,1,1,-2}
$$

is in the kernel. Comparing this with Lemma 3.2, this accounts for all terms of the decomposition of $H^{2}(U, \mathbb{Q})$. This completes the proof of Theorem 1.2 for IA.

Recall that the map

$$
\tau^{(2)}: \mathrm{IA}^{(2)} \longrightarrow \operatorname{Hom}\left(H, F^{(3)} / F^{(4)}\right)
$$

factors through $\mathrm{IA}^{(2)} / \mathrm{IA}^{(3)}$. The proof of Therem 1.2 together with the computations of subsection 3.2 imply that as $\mathbb{Q}$-vector spaces:

$$
\mathrm{IA}^{(2)} / \mathrm{IA}^{(3)} \otimes \mathbb{Q} \simeq \Phi_{0,1,0, \ldots, 0} \oplus \Phi_{1,1,0, \ldots, 0,1,-1} \subset \tau^{(2)}\left(\mathrm{IA}^{(2)} / \mathrm{IA}^{(3)}\right) \otimes \mathbb{Q}
$$

Therefore the map

$$
\tau^{(2)} \otimes i d: \mathrm{IA}^{(2)} / \mathrm{IA}^{(3)} \otimes \mathbb{Q} \longrightarrow \operatorname{Hom}\left(H, F^{(3)} / F^{(4)}\right) \otimes \mathbb{Q}
$$

is injective. Tensoring with $\mathbb{Q}$ kills only torsion, so this completes the proof of Theorem 1.3 for IA.
From the definitions, the kernel of $\tau^{(2)}$ is exactly $K_{n}^{(3)}$, so it follows from Theorem 1.3 that $K_{n}^{(3)}$ contains IA ${ }^{(3)}$ as a finite index subgroup. That they are equal when $n=3$ follows from computations to come in Section 3.5. As $K_{n}^{(2)} / K_{n}^{(3)}$ is a free abelian group, its rank is equal to the dimension of the image of $\tau^{(2)} \otimes i d$ in $\operatorname{Hom}\left(H, F / F^{(3)}\right) \otimes \mathbb{Q}$, which can be computed using the Weyl character formula (see [FH, page 400]). This concludes the proof of Corollary 1.4.
We now turn our attention to OA, beginning with an analogue of Theorem 1.1. Recall that OA is equal to $\mathrm{IA} / \operatorname{Inn}(F)$, the quotient of IA by the inner automorphisms of $F$. The equivariance of $\tau$ with respect to the action of $\operatorname{Aut}(F)$ implies that $\operatorname{Inn}(F)$ maps to a $\mathrm{GL}(n, \mathbb{Z})$-submodule of $\wedge^{2} H \otimes H^{*}$. Thus we obtain an $\operatorname{Aut}(F)$-equivariant map $\bar{\tau}$ defined on OA having as its image the quotient of $\wedge^{2} H \otimes H^{*}$ by the image of $\operatorname{Inn}(F)$. Note that $\operatorname{Inn}(F)$ is generated by the elements

$$
g_{k 1} g_{k 2} \cdots g_{k n} \quad 1 \leq k \leq n
$$

and so its image in $\bigwedge^{2} H \otimes H^{*}$ is generated by the elements

$$
\sum_{i=1}^{n} e_{k} \wedge e_{i} \otimes e_{i}^{*} \quad 1 \leq k \leq n
$$

There is an injective homomorphism

$$
H \longrightarrow \wedge^{2} H \otimes H^{*}
$$

given by mapping the generators $e_{k}$ to

$$
e_{k} \mapsto \sum_{i=1}^{n} e_{k} \wedge e_{i} \otimes e_{i}^{*} \quad 1 \leq k \leq n
$$

So $\bar{\tau}$ is the homomorphism

$$
\bar{\tau}: \mathrm{OA} \longrightarrow\left(\bigwedge^{2} H \otimes H^{*}\right) / H
$$

with kernel [OA, OA].
Similarly there is a "higher" Johnson homomorphism for OA. The homomorphism $\tau^{(2)}$ maps $\operatorname{Inn}(F)$ to the submodule of $\left(\bigwedge^{2} H \otimes H / \bigwedge^{3} H\right) \otimes H^{*}$ generated by (equivalence classes) of the form

$$
\sum_{i=1}^{n}\left(e_{j} \wedge e_{k} \otimes e_{i}\right) \otimes e_{i}^{*}
$$

There is an injective homomorphism

$$
\begin{gathered}
\wedge^{2} H \longrightarrow\left(\bigwedge^{2} H \otimes H / \bigwedge^{3} H\right) \otimes H^{*} \\
e_{j} \wedge e_{k} \mapsto \sum_{i=1}^{n}\left(e_{j} \wedge e_{k} \otimes e_{i}\right) \otimes e_{i}^{*}
\end{gathered}
$$

and so there is a homomorphism

$$
\bar{\tau}^{(2)}: \mathrm{OA}^{(2)} \longrightarrow\left(\left(\bigwedge^{2} H \otimes H / \bigwedge^{3} H\right) \otimes H^{*}\right) / \bigwedge^{2} H
$$

Now arguments previously applied to IA complete the proofs of Theorems 1.2 and 1.3.

### 3.5 Towards computing the kernel of $\tau^{*}$ on $H^{3}(U, \mathbb{Q})$.

At this stage, it should be possible to find cocyles in $H^{3}(\mathrm{OA})$ using Theorem 1.2 and the method of Sakasai [Sak]. However we are not yet equipped to take this step for IA because, although we know the isomorphism classes of terms in the kernel of $\tau^{*}: H^{2}(U, \mathbb{Q}) \rightarrow H^{2}(\mathrm{IA}, \mathbb{Q})$, these classes appear with multiplicity
greater than one in the decomposition of $\wedge^{2} U_{\mathbb{Q}}^{*}$. To follow Sakasai's method for computing the kernel in $H^{3}(U, \mathbb{Q})$ of $\tau^{*}$, we would first need to find explicit highest weights for the simple modules in the kernel. We do this for the case $n=3$.

The set of nine Magnus generators of $\mathrm{IA}_{3}$ gives a set of 36 generators for the finite rank abelian group $\mathrm{IA}_{3}^{(2)} / \mathrm{IA}_{3}^{(3)}$. For distinct $i, j, k \in\{1,2,3\}$, the following elements of $\mathrm{IA}_{3}^{(2)} / \mathrm{IA}_{3}^{(3)}$ are equal to 0 :

$$
\begin{aligned}
& {\left[g_{i j}, g_{i k}\right]} \\
& {\left[g_{i j}, g_{k i}\right]+\left[g_{i j}, g_{k j}\right]} \\
& {\left[f_{i j k}, g_{i j}\right]+\left[f_{i j k}, g_{i k}\right]} \\
& {\left[f_{i j k}, g_{j i}\right]+\left[f_{i j k}, g_{j k}\right]} \\
& {\left[f_{i j k}, g_{k i}\right]+\left[f_{i j k}, g_{k j}\right]+\left[g_{i j}, g_{j i}\right]+\left[g_{i k}, g_{j i}\right]}
\end{aligned}
$$

where the "+" notation denotes multiplication in $\mathrm{IA}_{3}^{(2)} / \mathrm{IA}_{3}^{(3)}$. These relations imply that a minimal generating set for $\mathrm{IA}_{3}^{(2)} / \mathrm{IA}_{3}^{(3)}$ has no more than 18 elements. Since $K_{3}^{(3)}$ is equal to the kernel of $\tau^{(2)}$, the formula of Corollary 1.4 implies that 18 is the dimension of the image of $\mathrm{IA}_{3}^{(2)}$ in $\operatorname{Hom}\left(H, F_{3} / F_{3}^{(3)}\right) \otimes \mathbb{Q}$. As $\mathrm{IA}_{3}^{(3)}$ is contained in $K_{3}^{(3)}$, the list of relations must be complete. Notice that this implies the last claim of Corollary 1.4, that $K_{3}^{(3)}=\mathrm{IA}_{3}^{(3)}$, which was originally shown by Andreadakis [A].
Now we can identify explicit vectors in the image of $\operatorname{Hom}\left(\mathrm{IA}_{3}^{(2)} / \mathrm{IA}_{3}^{(3)}, \mathbb{Q}\right)$ in $\wedge^{2} H^{1}(U, \mathbb{Q})$. For example, the element

$$
\left(e_{2}^{*} \wedge e_{3}^{*} \otimes e_{3}\right) \wedge\left(e_{3}^{*} \wedge e_{2}^{*} \otimes e_{2}\right)+\left(e_{2}^{*} \wedge e_{3}^{*} \otimes e_{1}\right) \wedge\left(e_{1}^{*} \wedge e_{3}^{*} \otimes e_{3}\right)
$$

of $\wedge^{2} H^{1}(U, \mathbb{Q})$ which sends each of

$$
\left(e_{2} \wedge e_{3} \otimes e_{3}^{*}\right) \wedge\left(e_{3} \wedge e_{2} \otimes e_{2}^{*}\right)
$$

and

$$
\left(e_{2} \wedge e_{3} \otimes e_{1}^{*}\right) \wedge\left(e_{1} \wedge e_{3} \otimes e_{3}^{*}\right)
$$

to 1 and all other standard basis elements of $\wedge^{2} H^{1}(U, \mathbb{Q})$ to 0 is in the image of $\operatorname{Hom}\left(\mathrm{IA}_{3}^{(2)} / \mathrm{IA}_{3}^{(3)}, \mathbb{Q}\right)$.
